PRINTING, in the widest sense of the word, may be defined to be the art of producing copies of any writing or other marks by pressure, either upon a substance so soft as (like wax or clay) to take the shape, whether in relief or by indentation, of the stamp applied to it, and yet not so perfectly fluid (like water) as to refuse to retain the form so given to it; or upon a substance sufficiently bibulous or otherwise attractive as to receive colour from some pigment with which the stamp is daubed. The essence of printing is the production of a copy by pressure. Correctly speaking, however, it is not an exact copy or fac-simile which printing produces in any case; so far from that, wherever the surface is raised in the stamp, it is sunk in the impression, and *vice versâ*, and even a merely coloured mark is always reversed in form; but, what is alone of importance, all the impressions are exact copies of one another, and also bear a certain and perfectly assignable relation to the stamp or type.

Even on a theoretical view of the subject, printing by means of merely a variegated surface or stamp, or, in other words, the reproduction, in soft substances, of cameos and intaglios, would seem to be the simpler and more obvious of the two kinds of printing we have mentioned. This may be said to be printing by pressure alone. In the other kind of printing, by the transference of colour, there is required the introduction, in addition to the type and its recipient, of a third element or agent, namely, the colour to be transferred. And this was an addition very little likely ever to be made until the idea of multiplying copies of coloured marks had itself occurred, that is, until the very object had been thought of which this was the only means of accomplishing, and which was the only object this process was suited to accomplish. Having a seal or cut stamp in his hand, the making an impression with that upon wax or any other soft substance was extremely natural for a person wishing on any occasion to leave his mark or sign; it was the same thing, in fact, with notching a piece of wood or stone with a knife or other sharp instrument, with this difference only, that the knife makes its marks by excision, or altogether removing and abstracting part of the substance operated upon; the stamp, by extrusion, or merely pushing it aside. Or still more nearly it resembles the rudest and readiest of all ways of making a mark, namely, by dealing a blow. But it is a mode of making a mark only; that is its sole purpose and object. There is no thought, so long as this kind of printing exclusively is used, of multiplying copies of the same mark; that is an idea far removed from the first and most natural employment of a dry stamp or seal, and not perhaps more likely to be suggested by such stamping or sealing (although capable of being so realised) than by some other things—by the mere common process, for instance, of copying by imitation. If a transcriber had ever had before him a written page, with the ink not yet dry, which he was laboriously reproducing with his pen, the slowness of his procedure, especially if he were pursued by an active and growing demand on the part of the public for books, might have led him to the thought of the possibility of performing the whole task in a manner at once, by merely impressing the wet writing upon the blank paper, and then re-transferring it from the reversed copy thus made to another sheet, in order to recover the original position of the characters. And if by any means the reversed copy could be kept moist, or its moisture repeatedly renewed, here was a method of procuring in the same easy manner an indefinite number of copies. The mechanical facilities were still to be invented, but this was the elementary idea of what we have been regarding as the second kind of printing; which, it thus appears to us, would probably not be suggested by the first kind at all, but rather by the desire of effecting an object (namely, the multiplying of copies) altogether different from that (namely, the mere making of a mark) which was the primary purpose of a dry stamp or seal, and only presenting itself at a much later and more advanced stage in the progress of civilisation.

These considerations may help to account for the historic fact that the use of engraved seals for impressing soft substances preceded by so many centuries the invention of the art of printing by the transference of a pigment, or, in other words, by means of coloured stamps or types. Nevertheless the principle of an engraved or uneven surface might still for a particular purpose be called in to the aid of the process of pigment-printing, although it had nothing to do with the suggesting of that process. Suppose the writing which is to be transferred by such mode of printing to be traced in visible black characters upon a smooth surface of wood or metal, how is the pigment to be most conveniently renewed every time it gets dry or faint? With an even surface it is evident that this could only be done by the tedious method of retracing every line of the writing with a pen or brush, a method which—besides its consumption of time, making printing, in fact, as slow as writing—would probably be found to be inefficient, as leaving the page dry or half dry in one part before it could be inked over in another. But by either cutting hollows for the ink, or causing the characters to stand out in relief, the great advantage is gained of being able to spread the pigment by a few sweeps of the brush along every line which it ought to colour, without leaving any of it upon the intervening parts of the wood or metal: in the case of hollow lines being cut (as in copperplate-printing), the ink that is spread in the first instance over the whole surface is easily wiped away from the rest without being taken out of the hollows.

At this point, then, we may be said to have at last obtained the art of printing in a practical shape. The art was now invented. This is precisely the art of printing as it has been known in China since the middle of the 10th century, when it is said to have been discovered by a minister of state named Foong-taon, and as it is still practised there. The page of writing to be multiplied is pasted down upon the smooth surface of a prepared block, commonly of pear-tree, on which it leaves an impression of the characters in an inverted form, and then the block thus marked is made ready to be printed from, by cuting away all the blank parts of the face of the wood, and the lines forming the characters are thus left in relief, so as alone to receive the ink every time the brush is applied.

In such a language as the Chinese, which is without an alphabet, or at least in which the elementary characters have not been reduced to the same limited and commodious number as in most other languages, by making them represent sounds instead of ideas or things, this, or the lithographic process, are the only kinds of printing that are generally applicable. The subsequent improvements or extensions of the principle are all dependent upon the common alphabetic mode of writing.

Even in Europe, however, although the mode of writing was alphabetic, it was the Chinese mode of printing that was first practised. Some have even supposed that the knowledge of the art was originally obtained from the Chinese; and indeed, besides what other less direct communication there may have been, Marco Polo, who returned from China about the end of the 13th century, had seen and described at least one application of the invention in that country, the fabrication of a species of paper-money by stamping it with a seal covered with cinnabar (vermilion). But, as far as we can trace, it was not till fully a century after this that even this simplest kind of printing began to be practised in Europe. It appears to have been first applied to the fabrication of playing-cards and manuals of popular devotion, the latter for the most part consisting, like the cards, of merely a single page, though in some instances assuming the form of little books of several pages. It is believed that about the year 1400, or soon after, both these articles, which had previously been manufactured by hand, and each copy of course by a separate operation, began to be multiplied, like the Chinese paper-money, from engraved blocks or stamps. There is no record of this innovation, but the fact is inferred from the perfect similarity of several copies of the same page, which could only have been produced by their having all been impressions from a common original. The playing-cards thus fabricated are merely pictures; but many of the devotional manuals, besides pictures, which in these also fill the greater part of each page, present short texts from Scripture, and other examples of engraved letters and words. It is evident, however, that the essence of the new art is as much in the pictures as in the legends, which are only pictures of another kind.

The æra of these block prints and books, as they are called, may be stated to be the first half of the 15th century: one in Lord Spencer's collection bears the date of 1423, and there is reason to believe that other specimens were executed almost as late as 1450. Of the block-books of any considerable magnitude the two most remarkable are, that generally styled, though probably not correctly, the 'Biblia Pauperum,' a small folio of forty leaves, each containing a picture, with a text of scripture or some other illustrative sentence under it, the first edition of which (for there were several), is supposed to have been produced between 1430 and 1450, and of this an early edition is in the King's Library of the British Museum; and the 'Speculum Humanæ Salvationis,' consisting of sixty-three leaves of the same small folio size, containing in all fifty-eight pictures, with two lines of Latin rhyme under each. With regard to this last in particular, however, there has been a great deal of disputation, some denying altogether its claim to be reckoned a specimen of block-printing, in so far as the legends are concerned; but it is now generally admitted that at least some of the legends have every appearance of having been printed from the same block with the picture, although in other cases they seem to have been subsequently inserted from moveable types. A minute examination of the cuts, undertaken by Mr. Ottley, has proved that the Latin edition with moveable types was undoubtedly the earliest, and dates probably about 1470. The edition in which twenty of the subjects have the inscriptions cut on the wood, while the others are from moveable types, is apparently a copy ("laid down," as engravers style it) of the original Latin edition. Another block-book that was frequently printed, and which is noticeable as consisting wholly of text, without pictures, was the small Latin Grammar of Donatus, the common school-book of those days. These block-books are, like the Chinese books at this day, printed only on one side of the leaf, and may have been produced in Germany.

At this point, as we have already observed, printing would have stopped, if the art of alphabetic writing had remained undiscovered. At most, the art could not have been carried beyond what has been called logography, or the printing with types, each containing a whole word, a method which is in partial use in China, and has even in recent times been attempted among ourselves, but which is manifestly of very limited application. Logography, indeed, is merely a modification of block-printing; the principle is the same whether the block or type contain a whole word, a whole line, a whole sentence, or a whole page.

It is not unlikely, however, that the partial employment of logography in the infancy of European printing may have been what suggested alphabetic printing. There is good evidence that some words of common occurrence were early cut out on separate stamps or types; and although this may have been done only after the invention of alphabetic printing, to save the trouble of composition (or setting up the words from the letters), it is possible that the same thing may also have been done while only block-printing was known, with the view of saving the repeated cutting out of the same words. If so, the perception, thus awakened and turned to account, of the fact that two different pages often contained some words in common, would be apt, it may be thought, to conduct to the reflection that all words and all pages that could be printed were composed out of the same twenty-four letters, and that therefore if a sufficient number of types consisting each of a single letter could be provided, the same types that had been made use of in printing any one page might, with the mere trouble of re-arrangement, be made to serve for printing any other. Here was what we may call quite a new principle. Logography was indeed the employment to a certain extent of moveable types; but the principle of moveable type printing was no more there than we can say the principle of alphabetic writing is to be found in the 214 radical characters of the Chinese. The universality which is the essence of a principle is equally wanting in both cases.

Yet, whether it may have been arrived at through the medium of logography or not, it may be safely affirmed that, where alphabetic writing was known, alphabetic printing could not be long in being found out. It was in fact, in a manner, already invented, in the coexistence of pigment printing on the one hand, and of alphabetic writing on the other; for it was the mere resultant, without the assistance of any third element, of the combination of these two ideas. Not that even this simple combination would of necessity be immediately made; the history of discovery sufficiently attests that it will often be a considerable time before a third thing is thought of which would be at once accomplished by the mere bringing together, and into simultaneous and accordant action, of two things already familiarly known and practised; but still, fortuitously, or through reflection and experiment, the new idea is much more likely to be struck out in these circumstances than if a more complex combination were required to produce it, and, especially where the state of society supplies any considerable stimulus to the attainment of it, cannot be very long in being arrived at.

The common art of printing, in essentially the same degree of completeness in which we now possess it, had certainly been discovered before the middle of the 15th century; but when, where, and by whom each successive improvement of the original pigment-printing by means of engraved blocks was discovered and first put in practice is not so easily settled. The employment of moveable types, the production of such types by the process of casting them in metal, and the formation of the matrix, or mould, by means of the punch, or stamp of hardened steel by which the matrix is impressed or hollowed out; these, disregarding mere mechanical facilitations, may be considered as the three great organic changes by which block-printing was transformed into the art as it now exists. They are far, indeed, from being upon a level in point of importance; they descend in value in the order in which we have enumerated them, which must also have been the order in which they followed each other; and the third contributes so little to the completion of the invention, as compared with either the first or second, that we might perhaps without much injustice omit it altogether. Pigment stamping, the breaking up of the block-page into single letters, the substitution of letters of cast metal for those of cut wood, and the production of many matrices from one punch, the four successive steps constituting the invention of printing, have thus all one end and aim. This very circumstance might enable one of them in a great measure to suggest the next.

Simple as the first of the four successive discoveries—stamping or printing with a pigment—may be thought, it was perhaps both the most important and the most difficult to achieve of the whole. As for the three subsequent improvements, which constitute the whole portion of the art of printing indisputably invented in Europe in the 15th century, and to which alone the claims of the several individuals to whom the invention has been attributed have any reference, even the chief of them, the substitution of types containing each a single letter for blocks containing an entire page, must, we apprehend, be considered as inferior to the primary Chinese discovery in novelty, or real originality of conception, as it undoubtedly is in importance. That wonderful instrument, the alphabet, being already invented, this improvement consisted merely in chopping down the engraved wooden block into as many separate pieces as there were letters cut upon it. The casting of metal types again was only an application of the art of founding, which is one of the most ancient of the arts practised by men; and the fabrication of the matrix by a punch was merely an example of the familiar practice of receiving the impression of a stamp or seal upon a substance softer than itself, and precisely the same thing with the very common mode of stamping coins by hammering.

Four names have principally figured in the controversy that has been raised about the invention of printing:—John Gutenberg (paternally Gänsfleisch), of Strasburg; John Fust (or Faust), of Mainz; Peter Schöffer (in Latin, Opilio), of Gernsheim; and Lawrence Koster (or Janszoon), of Haarlem. Of all these, and of their claims to the invention, accounts will be found in the Biographical Division under their respective names.

An ancient chronicle, first printed at Cologne in 1499 ('Chronica, sive Fasciculus Temporum,' &c., commonly called the 'Cologne Chronicle'), notes that, after ten years had been spent in preparation, the art of printing began to be practised (cœptum est imprimi) in the year 1450. The knowledge of the art was first made public and carried into other countries by the dispersion of many of the workmen on the storming of Mainz by Adolphus of Nassau, in 1462. Printing was first practised in Italy, in the town of Subiaco, in the Roman territory, in 1465; in France, at Paris, in 1469; in England, at Westminster, in 1474; and in Spain, at Barcelona, in 1475. It is said that by the year 15 0 there were already about 200 printing-presses in Europe.

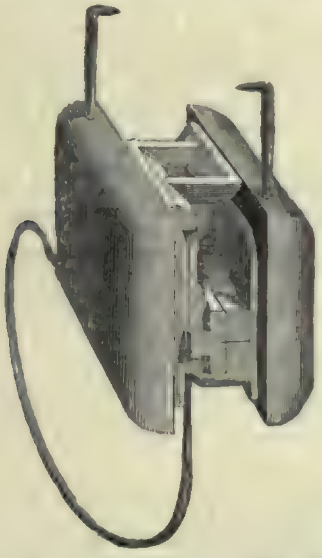
The following works relating to the invention of printing may be consulted with advantage: H. Junius, 'Batavia,' 1558, which contains the claim for Koster; P. Marchand, 'Histoire de l'Origine et des Progrès de l'Imprimerie,' 1740-41; P. S. Fournier, 'Dissertation sur l'Origine de l'Imprimerie,' 1759; M. Maittaire, 'Annales Typographicæ,' 1760; Jo. Dan. Schöpflin, 'Vindiciæ Typographicæ,' 1760; Baron Heineken, 'Idée Générale d'une Collection complète d'Estampes,' 1771; G. Fisher, 'Typographische Seltenheiten,' 1804; Singer, 'Researches into the History of Playing-Cards, with Illustrations on the Origin of Printing and Engraving on Wood,' 1816; W. Ottley, 'History of Engraving upon Copper and on Wood,' 1816; Dahl, 'Die Buchdruckerkunst erfunden von J. Gutenberg, verbessert und zu Vollkommenheit gebracht durch P. Schöffer,' 1832; Jackson and Chatto, 'Treatise on Wood Engraving,' 1839; C. Knight, chiefly with reference to the introduction of printing into England, 'The Old Printer and the Modern Press,' 1854; and W. L. Sotheby's costly work on 'Early Block Books,' 1859.

Of the important effects produced by this great discovery, and of the progress made in civilisation by the diffusion of books, it is not our province to treat here. We proceed to describe the mechanical processes connected with printing. For very many years these processes received few improvements; but from about the commencement of the present century they have been numerous and important. We shall therefore treat of them in the order in which they may be said to occur in their uses in a modern printing-office. These are *Type-founding; Composing; Printing Presses and Printing Machines;* and *Stereotyping.* To these as connate subjects we shall add *Printing for the Blind; Nature Printing* or *Autotypography;* and *Printing by Collins's Patent Process.*

Type-founding.—After the invention of Schöffer, the apparatus employed appears, at a very early period, to have assumed its present form. The first satisfactory evidence upon this point is afforded by the device of Badius Ascensius, an eminent printer of Paris and Lyons, at the beginning of the 16th century; which device was subsequently adopted, with various modifications, by several other printers, among whom was an English practitioner, Anthony Scoloker, of Ipswich. It exhibits the various operations then usually carried on at a printing-office, embracing type-founding as well as composing and printing; and it represents the matrix and other apparatus of the type-founder in the form still used. Most of the early printers, in England as well as on the Continent, cut and cast their own types; and Aldus Manuzio, towards the end of the 15th century, distinguished himself by the elegance of his type, and invented that now called italic. [Manuzio, Aldo, in Biog. Div.] One of the earliest notices of that division of labour which has tended so greatly to the improvement of the art, is found in a decree of the Star Chamber, dated July 11, 1637, intended to suppress or render more difficult the publication of seditious works by the Puritans and others opposed to the government, who, about that period, established secret printing-offices for the purpose. This decree ordained that there should be only four founders of letters for printing in the kingdom; and that any vacancies which might occur in that number should be filled up by the archbishop of Canterbury or the bishop of London, and six other high commissioners; and it laid the most stringent regulations upon the master-founders respecting the employment of journeymen and the taking of apprentices. These oppressive restrictions were re-enacted for two years, by an Act of Parliament of the 14th year of Charles II., and renewed for limited periods in his 16th and 17th years. They were again revived for seven years in the 1st year of James II., 1685, and finally expired, on the termination of the last-mentioned term, in 1693.

Although Caxton and Wynkyn de Worde had, in the infancy of English printing, established a high character as type-founders, this branch of the art long remained in a depressed state in England, the best types being supplied by continental founders; a circumstance which may, perhaps, be attributed in some degree to the restrictions imposed upon the British founders after their art was separated from that of printing. At the commencement of the 18th century native talent was at so low an ebb, that all the types used by London printers for superior works were imported from Holland. William Caslon, who was originally employed in engraving on gun-barrels, and in cutting ornaments and letters for the use of book-binders, has the honour of removing this stigma upon English ingenuity. Having executed some remarkably neat letters for lettering books, he was induced to attempt punch-cutting; his first engagement in this way being for the Society for Promoting Christian Knowledge, for whom he executed an Arabic fount about the year 1720. Caslon was encouraged and assisted by Bowyer; and he soon attained a reputation which not only put an end to the importation of Dutch types, but occasioned a demand for his own on the Continent. His foundry was continued by his descendants, and is still in operation. Another name memorable in the history of English type-founding is that of John Baskerville, of Birmingham, who died in 1775. His stock of beautiful types was sold to a literary society in Paris, and used for printing a splendid edition of the works of Voltaire; his widow having failed to obtain either a purchaser in England, or sufficient encouragement to induce her to continue his business. The history of the early British founders is minutely given in a very rare pamphlet, published in 1788, by the eccentric Edward Rowe Mores, entitled 'A Dissertation upon English Typographical Founders and Founderies;' and Hansard, in his 'Typographia,' has reprinted most of the information collected by Rowe Mores, together with notices of more recent type-founders. In France the names of Breitkopf and Didot attained high celebrity for improvements in type-founding. The Imperial printing-office at Vienna, where punch-cutting and type-founding are carried on, possesses probably the most numerous collection of foreign alphabets having distinct characters.

The first and most important operation of a type-foundry is the formation of the punches, which are well-tempered pieces of steel, each of which bears on its face a single letter, formed with the greatest possible accuracy by filing, cutting, and punching the hollows with smaller punches. The face of the punch exactly resembles that of the finished type: the letter being reversed, and in high relief. The punch-cutter, in addition to the care and judgment required for making the letter of precisely the right size, form, and thickness, so that it may range well with other letters of the same *fount* or set, must consider the best degree of slope for the sides of the letter, so that, on the one hand, he may avoid making them so vertical that the lines will be weak, and easily broken or battered; and, on the other, that they may not, owing to too rapid an increase of thickness towards the base, produce a thick blurred impression when printed from. When the punch is completed and hardened, it is struck into a piece of copper, which, when it has received the impression from the end of the punch, is called a *matrix*, and forms a mould for the face of the type. The striking of the matrix, like every other operation in the formation of the mould, requires great nicety, because, if the punch be not held perfectly vertical, the face of the type will not be at right angles with its sides, and the impression will consequently be uneven. The depth of the impression is also of consequence, as it affects the height of the type; but this may be regulated by filing the face of the matrix. The sides and end of the matrix are then accurately squared; perfect truth in this respect being necessary, in order that, when the matrix is adjusted in the mould, the letter may be perfectly square with that portion of it which is to form the shank, or *body* of the type, and may also have its proper position with reference to the top and bottom of the body; so that when the types are set up together and printed from, the letters may not only be upright, but may also range in a perfectly straight line. The *mould*, of which a representation is annexed, consists of two halves, each of which is made of steel, and attached, for convenience of holding, to a piece of wood. The two halves of the mould are so formed, with projecting blocks and recesses to receive them, that they may be instantaneously fitted together, as shown in the cut, leaving a square funnel-shaped opening at the top, by which the type-metal is poured in, and below it the actual mould for the body of the type, with the matrix at the bottom to form the letter or face of the type. The two halves of the mould are so constructed that they will slide a little upon each other, laterally, so as to vary the thickness of the body of the letter, that the same mould may be used, with different matrices, for casting every letter of a fount, from i or l, which have very narrow bodies, to m or w, which have wide bodies. The type-metal is usually melted in a small cast-iron pot, set in brickwork with an enclosed fire under it, and is poured into the mould by a very small ladle. The caster then jerks the mould quickly upwards by a peculiar motion of his arm, and thereby expels the air, and forces the fluid metal to enter the cavities of the matrix. When the metal is set, the caster removes the pressure of the long curved spring at the bottom of the mould, and thereby relieves the matrix from the face of the type. The mould is then separated, and the type is removed by the application of one of the hooks attached to the upper part of each half. Complicated as these operations appear in description, the closing of the mould, casting the type, releasing the spring, opening the mould, and removing the type, are all performed in about the eighth part of a minute; so that an expert workman will cast 500 letters in an hour.



When the types leave the caster, each of them has a small block of metal attached to its shank, being that which filled the throat or funnel of the mould. These are removed by a boy, who takes up the types by their edges, or rather by the top and bottom of the body, and breaks off the superfluous metal by a motion almost too quick to be followed by the eye. The average number thus treated in an hour is 2000, but some boys can break off about 5000. The next operation is rubbing the flat sides (but not the edges) of the types upon a piece of gritstone, the fingers of the rubber being protected by pieces of tarred leather: this also is commonly done at the rate of 2000 per hour. The types are then set up by boys in long rows or lines, and these are firmly secured in long frames, which hold them together while the dresser scrapes or polishes the flat surfaces which form the top and bottom of the body, and cuts a groove or channel along their lower ends by means of a small iron plane. While they are in the frame the types are also *bearded*, an operation which consists in planing away to a bevel the upper angle of the body at the feet of the letters. After dressing the types are tied up in such lines as may be convenient, and the proportionate numbers of every type of which a fount consists are selected. All the types belonging to one fount are distinguished by one or more grooves or *nicks* across the lower edge or bottom face of the body, by which simple contrivance the compositor is enabled to see, or even to feel, without looking at the face of the letter, when a type is inverted. These nicks, which should be different in number or position in each fount used in a printing-office, are formed by the insertion of one or more wires in the mould, or they are cut by a plane while they are in the long frames.

Although the composition of type-metal varies greatly in different countries, and even in the practice of different British founders, lead almost invariably forms the principal ingredient. Some of the earliest founders are supposed to have used iron to harden it; but in modern times regulus of antimony is commonly employed for the purpose. Different founders use different alloys, and in different proportions, and this frequently forms a trade secret. The size of the type also occasions a difference, as a small type requires to be harder than a large type.

An invention has also been introduced by which a coating of copper is given to the face of the type by an electro-galvanic process, rendering it much more durable at a moderate expense.

Some letters, from their peculiar form, require more care than others, owing to the projection of certain prominent points beyond the shank or body of the type. Such are called *kerned* letters; and, from their greater liability to injury, rather more than a due proportion of them is cast with a fount. In the common Roman alphabet, f and j are the only kerned letters; but in an italic fount, *d*, *g*, *j*, *l*, and *y* are kerned on one side, and *f* on both sides, and some of the capitals also. As the kerned f cannot be placed close to another f, an i, or an l, it becomes necessary to cast what are called *logotypes*, or types containing two or more letters cast on one body. Those in common use are ff, fl, fi, ffi, and ffl. An attempt was made on a very extensive scale in the last century to introduce the use of types bearing whole words or syllables, under the name of *logography*, or *logographic printing*, but although an edition of Anderson's 'History of Commerce,' in four quarto volumes, 1787–9, and some other works, were printed in this way, the scheme was eventually abandoned.

As the several letters of the alphabet are, in common printing, required in very different proportions, the number cast of each letter in a fount needs to be carefully regulated. The proportions vary in different languages, and in different kinds of work; but for ordinary English book-work they are about as follows:—

a	8500	n	8000	ff	400
b	1600	o	8000	fi	500
c	3000	p	1700	fl	200
d	4400	q	500	ffi	150
e	12,000	r	6200	ffl	100
f	2500	s	8000	æ	100
g	1700	t	9000	œ	60
h	6400	u	3400	,	4500
i	8000	v	1200	;	800
j	400	w	2000	:	600
k	800	x	400	.	2000
l	4000	y	2000	'	700
m	3000	z	200		

To the above are added accented and dotted letters, in numbers ranging from 100 to 250; numerals 1 to 9, and 0, from 1000 to 1300 each; and notes or marks of reference, parentheses, brackets, &c., in number varying from 60 to 300. The number of CAPITALS supplied with such a fount ranges from the lowest number, 80 (Z), to the highest, 800 (I), with 40 of Æ and 30 of Œ. Of SMALL CAPITALS, the number required in ordinary cases is about one-half that of large capitals; and *Italics* are also supplied in small numbers. Spaces, which are pieces of metal resembling the shanks or bodies of letters, and used to separate words, are cast of various thicknesses, to enable the compositor to *justify* his work, or to fill-up each line to the same degree of tightness, by varying the spaces between the words. Of the smallest kind, which are called, from their extreme thinness, *hair-spaces*, 3000 are supplied with a fount of the above extent. Of the three next sizes, called *thin*, *middle*, and *thick spaces*, the numbers are 8000, 12,000, and 18,000 respectively. The next in order are n-*quadrats*, or spaces equal in body to the letter n, of which 5000 are required; and m-*quadrats*, double in thickness to the last, and similar in body to the letter m, which is exactly square, or as wide as it is deep, of which the number is 2500. In addition to these are larger quadrats, equal in body to two, three, or four m's, which are used for filling up lines at the end of a paragraph, or in poetry, and for setting up blank lines in order to separate two paragraphs. These are supplied by weight, according to the kind of work for which the fount is required.

Although all British founders employ the same names for types of similar size, it is to be regretted that perfect uniformity in the sizes is not sufficiently attended to to allow the types of different foundries to be used together without inconvenience. The subjoined specimens show the various sizes employed in England for book-work, beginning with the largest, and descending to the most minute:—

1. *Great Primer* is the largest type ever used for printing books. It is seldom employed for anything excepting large folio Bibles, and on this account is sometimes called *Bible Text*. The French call this type *Gros Romain*, and the Germans, from its having been the third of seven sizes formerly used, name it *Tertia*. About 51½ m's in width, or the same number of lines in depth, occupy a foot.

2. *English*, called by the French and Dutch *St. Augustin* (from which it is supposed to have been first used for printing the works of that author), and by the Germans *Mittel*, as the middle of the seven sizes above alluded to, is used for printing Bibles and other works in folio and quarto. There are about 64 m's to a foot.

3. *Pica*. This type is much used for printing the text of standard library works, and is generally referred to by printers as a standard for the measurement of work. Leads, brass-rules for printing lines, braces, or quotations, &c., are always made to so many Pica m's, whether used with this type or not. In France and Germany it bears the name of *Cicero*, apparently from having been originally used in printing his Epistles. 71 Pica m's go to a foot.

4. *Small Pica*, called *Philosophie* in France, and *Brevier* in Germany, is a type very extensively used; perhaps more than any other. About 83 m's go to a foot.

5. *Long Primer*. This neat type, which is much used for printing works in duodecimo, is called *Petit Romain* in France, and *Corpus* in Germany; the latter name being probably derived from its use in printing the 'Corpus Juris:' 89 m's of Long Primer go to a foot.

6. *Bourgeois* appears, by its name, to have come originally from France; but the French type which comes nearest to it is now called *Gaillarde*. Hansard states, in the article 'Type-founding,' in the 'Encyclopædia Britannica,' that the Germans have no type corresponding with this. It is half the size of Great Primer, and about 102 m's go to a foot.

7. *Brevier*, called in France *Petite Texte*, and in Germany *Petit* or *Jungfer* (maiden letter), derives its English name, most probably, from its having been first used for printing breviaries, or Roman Catholic church-books. It is employed for printing small works, and for notes to those printed in larger type. About 112½ m's go to a foot. It is a type very much used, and is that employed for the text of the 'English Cyclopædia.'

8. *Minion* (French, *Mignonne;* German, *Colonel*) is used principally in newspapers, although some Bibles and prayer-books, and pocket editions of other works, are printed in it. It is half the size of English; and 128 m's go to a foot.

9. *Nonpareil* (French and German *Nonpareille*). Hansard observes of this beautiful type, that at its introduction it was, of course, without a peer in comparative size to the larger types; and he thinks that it still retains its character, and that every smaller type is below the compass that any eye of medium sight is able to read without pain. It is employed in the foot-notes occasionally introduced in this work. Its size is half Pica; and 143 m's go to a foot.

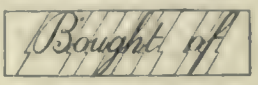
10. *Ruby* is a somewhat irregular size introduced by English founders subsequently to the smaller types given below, and is employed for pocket dictionaries, Bibles, prayer-books, &c. Hansard states that it was originally a Nonpareil with short ascenders and descenders, cast on a smaller body, or sometimes a Pearl, cast on a larger body, to give it an open appearance. The body of Ruby is about half that of Long Primer, and about 163 m's go to a foot.

11. *Pearl*, called by the French *Parisienne*, and by the Germans *Perl*, was the size cut next to Nonpareil. It is a beautiful letter for printing miniature editions, and is sufficiently clear to be read with facility by persons of strong sight. It is also much used for notes to books printed in larger type. Pearl is half the size of Long Primer; and about 178 m's go to a foot.

12. *Diamond*, to which the same name is given in France and Germany, is the smallest type used in this country, and is rarely employed excepting for Notes. Books printed wholly in this letter are typographical curiosities, and require the greatest possible care in printing. The stereotyping of Diamond type was formerly deemed impracticable, but it has of late years been successfully accomplished. The difficulty of making and composing type so exceedingly minute may be conceived from the fact that about 2800 of the letter i go to a pound weight, and about 5000 of the thinnest space. Henri Didot, the eminent French type-founder, cut a type smaller than the English Diamond, his fount being half Nonpareil, while Diamond is half Bourgeois; and Hansard states, in his 'Typographia,' that Mr. [illegible], who cut the Diamond of the Caslon foundry, commenced a size or fount to rival that of Didot. From the same authority it appears that the Dutch were the first in Europe to cut Diamond type, and Mr. Fry the first in England.

Of types larger than those employed for book-work, the first, in an ascending series, is called *Paragon;* the next is *Double Pica*, which is twice the size of Small Pica; above which are *Two-line Pica*, *Two-line English*, *Two-line Great Primer*, and *Two-line Double Pica*, each of which is double the size of the common type from which its name is taken. One other type, *Canon*, has also a distinctive name; but all above it are called, according to the number of Pica m's in their height, *Five-line Pica*, *Six-line Pica*, &c. Large letters, such as are used in posting-bills, were formerly cast in sand-moulds, and hence called *sand-letters;* but the fourth William Caslon introduced a convenient method of making matrices for such types, without the use of punches, by cutting the letter completely through a piece of copper or brass from one-eighth to one-fourth of an inch thick, making the apertures wider on one side than on the other; and then riveting the plate so cut with the face (or side at which the apertures are smallest) downwards upon a smooth surface of brass, which forms the face of the letter. They are now usually cut on a soft wood, for the special purpose required.

Ornamental types are made in endless variety for printing cards and circulars, and for other fancy purposes; but of these it is only necessary to mention particularly what is called *Script* type, which is cut to imitate writing. The early attempts to imitate cursive characters by letters cast upon a square body were very clumsy, it being impossible under such circumstances to give an easy inclination to the letters, and to make them join neatly. To remedy this M. Firmin Didot invented types with a body the sides of which form oblique angles with the top and bottom, and are so formed that they will, nevertheless, lock firmly together, without any inclination to slide upon each other. This may be readily understood from the annexed cut, which represents the words "Bought of" set up in script type, with a triangular piece of metal added at each end to allow of their being wedged up with type or quadrats of the usual form. Didot cast, on bodies of this form, the component parts of letters; but his idea was improved upon by English founders, who cast the letters complete, and provide for every variety of junction which may be required by casting some of the letters of different bodies, according to the relative positions they may be required to occupy. More recently, some founders have succeeded in casting types on a square body, which answer the same purpose as Script, and these, on account of the greater facility of composition, are more generally used for common work.



Many schemes have been suggested for facilitating the manufacture of types by the use of machinery; but as these have failed to come into general use, they may be dismissed with a very brief notice. One of the earliest formed part of a very comprehensive project for the improvement of printing brought forward by Mr. William Nicholson, editor of 'Nicholson's Journal,' about 1790. Another, which was patented about 1823, by Dr. William Church, of Birmingham, proposed to cast types at the rate of 75,000 per hour, and to melt and recast them after each time of printing from. A third, of less pretensions, as it did not propose to dispense with the subsequent rubbing and dressing, was the process of Henri Didot, patented in England by Louis John Pouchée, for casting at the rate of 24,000 per hour; which has been practised, although it did not supersede the ordinary mode of casting by hand.

More recently an ingenious machine has been invented. In this, by turning a crank-wheel, the metal is injected with considerable force into the type-mould, brought by the machinery in front of a reservoir of metal kept fluid by a gas-fire beneath it, and by a continued movement is delivered out of it, at a rate varying from six to ten times the rapidity with which the operation can be performed by hand. Both in casting by hand, and in the machine, the mould is liable to become obstructed by particles of the metal remaining, when it has to be brushed clean. When this happens to the machine, it ceases to act, and thus at once informs the operator of the defect.

Composing.—The processes in the business of a compositor are distributing and composing.

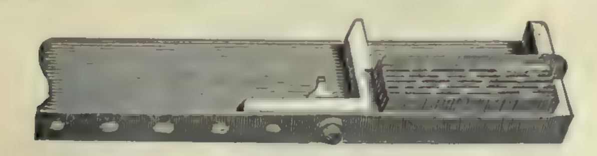
1. *Distributing.*—Each compositor works at a sort of desk called a frame, and in most instances he has the desk or frame to himself. The frame projects laterally from the wall, having the light on the left hand, unless when lighted from the top. The front and lowest part of this frame is about as high as the elbow or ribs of the compositor, in order to allow his arm to move freely over it. The back is about a foot or 15 inches higher. The space between is about 28 inches, and is divided into two inclinations. Upon the lower and flatter of these rests the *lower-case;* on the upper and more acute inclination rests the *upper-case*. Each frame is constructed to hold two pair of *cases*. Each pair of cases contains all the letters of the alphabet, whether small letters or capitals, as well as points, figures, &c., &c. One of these pairs

of cases is usually occupied by the *Roman* letters, the other by the *Italic*. The upper-case is divided into 98 partitions, all of equal size; and these partitions contain two sets of capital letters, one denominated "full capitals," the other "small"; one set of figures; the accented vowels; and the marks of reference for notes. The lower-case is divided into partitions of four different sizes, some at the top and ends being a little smaller than the divisions of the upper-case, others nearer the centre being equal to two of the small divisions, others equal to four, and one equal to six. In all, there are 53 divisions in the lower-case. The inequality in the size of the cells of the lower-case is to provide for the great differences as to the quantity required of each letter.

The proportion in which a particular letter is required renders it necessary that the cells of the lower-case should be arranged, not as the letters follow each other alphabetically, but that those in most frequent use should be nearest the hand of the compositor. The point at which he stands is not far removed from the centre of the lower-case, and within a range of about six inches on every side lie the c, d, e, i, s, m, n, h, o, p, u, t, a, and r, the letters in most frequent use. The spaces, which he wants for the division of every word, lie close at his hand at the bottom of the central division of the lower-case. It must be quite obvious that the man who contrived this arrangement saved a vast deal of time to the compositor.

As *distributing* is a part of the compositor's business for which nothing is paid direct (the payment for that labour being included in the price of composition), it is necessary, before he can compose, that he should put type into his cases, as no one will have done this for him. This operation is a most beautiful process in the hands of an expert compositor; and probably no act which is partly mental and partly mechanical offers a more remarkable example of the dexterity to be acquired by long practice. The workman, having prepared a quantity of type which has been already printed from, either in a form or page (terms which will be described under *making-up*, &c.), loosens the lines sufficiently to allow them to be washed free from dirt. While the types are yet moist, in which state they adhere sufficiently to prevent them with care from falling asunder, he lifts a portion of the type as it has been arranged in lines upon a slip of brass rule. This he rests upon the middle finger of his left hand, supporting one side with his thumb, towards which he somewhat inclines the whole handful. In each letter there is a nick or nicks, to indicate the bottom edge of the letter. Keeping the face towards him, and the nick uppermost, he takes up one or two words between the fore-finger and thumb of his right hand, and drops the letters, each into its proper place, with almost inconceivable rapidity. His mind has to follow the order of the letters in the words, and to select the box into which each is to be dropped, while his fingers have to separate one letter from another, taking care that only one letter is dropped at a time. This is a complicated act; and yet a good compositor will distribute three or four times as fast as he composes—that is, he will, if necessary, return to their proper places 50,000 letters a day. The letters being inverted in printing, are not read as they are read in a book, and thus "to know his p's from his q's" is a difficulty to a beginner.

Standing before the pair of cases which contain the Roman letter, he holds in his left hand what is called a *composing-stick*. This is a little iron or brass frame, one side of which is moveable, so that it may be adjusted to the required width of the page or column which the workman has to set up. It is made perfectly true and square; for without such accuracy the lines would be of unequal length. It is adapted to contain not more than about seventeen lines of the type of the present work.



Composing-Stick.

The copy from which the compositor works rests upon the least-used part of the upper-case. The practised compositor takes in a line or two at a glance, always provided the author writes an intelligible hand—which virtue is by no means universal. One by one, then, the compositor puts the letters of each word and sentence into his stick, securing each letter with the thumb of his left hand, which is therefore continually travelling on from the beginning to the end of a line; the letters being arranged on a thin slip of polished brass of the same height as the type, called a *setting-rule*, and which is shifted from behind each line to the front when completed, the roughness of the types being thus avoided. His right hand goes mechanically to the box which he requires; but his eye is ready to accompany its movements. In each letter, as we have stated, there is a nick or nicks, to indicate the bottom edge of the letter; and the nick must be placed outwards in his composing-stick. Farther, the letter must also be placed with the face upwards, so that two right positions must be combined in the arrangement of the types. If the compositor were to pick up the letter at random, he would most probably have to turn it in his hand; and as it is important to save every unnecessary movement, his eye directs him to some one of the heap which lies in the right position, both as regards the face being upwards and the nick being outwards. This nick is one of those pretty contrivances for saving labour which experience has introduced into every art, and which are as valuable for diminishing the cost of production as the more elaborate inventions of machinery. When he arrives at the end of his line, the compositor has a task to perform in which the carefulness of the workman is greatly exhibited. The first letter and the last must be at the extremities of the line: there can be no spaces left in some instances, and no crowding in others, as we see in the best manuscript. Each metal type is of a constant thickness, as far as regards that particular letter, though all the letters are not of the same thickness. The adjustments, therefore, to complete the line with a word, or at any rate with a syllable, must be made by varying the thickness of the spaces between each word. A good compositor is distinguished by uniformity of spacing: he will not allow the words to be very close together in some instances, or with a large gap between them in others. His duty is to equalise the spacing as much as he possibly can; and this is, in some cases, very troublesome. When the workman has *filled his stick*, as it is called,—that is, has set up as many lines as his stick will conveniently hold,—he lifts them out into what is termed a *galley*, by grasping them with the fingers of each hand, the setting-rule supporting them in front, and thus taking them up as if they were a solid piece of metal. The facility with which some compositors can lift about what is called a *handful* of moveable type, without deranging a single letter, is very remarkable. This sort of skill can only be attained by practice; and one of the severest mortifications which the printer's apprentice has to endure is, to toil for an hour or two in picking up several thousand letters, and then to see the fabric destroyed by his own clumsiness, leading him to mourn over his heap of broken type—technically called *pye*—as a child mourns over his fallen house of cards.

Letter by letter, and word by word, is the composing-stick filled; and by the same progression the galley is filled by the contents of successive sticks.

In composing pages for a book, when the compositor has set up as many lines as fill a page, he binds them tightly round with cord, and places them under his frame; this is *making-up*. We need scarcely say that the sizes of books greatly vary; but they are all reducible to a standard determined by the number of leaves into which a sheet of paper is folded. The most common size is called *octavo*, the size of Macaulay's 'History of England,' and this contains 16 pages to the sheet; the next is *duodecimo*, the size of the 'British Almanac,' containing 24 pages to a sheet; and the next *octodecimo*, or eighteens, containing 36 pages in a sheet. There are many other sizes, such as the larger *quarto*, which is the size of the present work, and the smaller *twenty-fours*. Much skill and ingenuity are employed in devising what are called schemes of imposition. In regular and perfect sheets of a work this is usually all settled, but in the endings of volumes the chances are much against their forming complete sheets, and the compositor has then to consider how he can best dispose the pages so as to avoid waste of paper and expense in working at press.

In every case, when a sheet is complete, the compositor arranges the pages in proper order upon the imposing-stone, which is a large table with a polished stone or iron top: he places around the whole a stout iron frame, called a *chase*, and surrounds each page with pieces of wood called *furniture*, so as to leave an equal margin to every page, and finally wedges the whole tightly together with a wooden mallet in the chase. If the work is properly executed, the pages thus wedged up, constituting one side of a sheet, termed a *form*, are perfectly tight and compact; and the *form* may be carried about with as much ease as if it were composed of solid plates, instead of being formed of 40,000 or 50,000, or even 100,000 moveable pieces, weighing from a few pounds to a couple of hundred-weight. In this state a *proof* is pulled; that is, a single impression is taken at the press.

In newspapers, periodical works, and many other works in which much alteration is anticipated in subsequent stages from the author, the type or *matter*, as it is technically called, is wedged in brass galleys, in what are called *slips*, and after it has undergone the process of correcting, it is then made up into pages and imposed, or arranged in order to be worked on the paper.

The inventive faculty has also been applied to methods for facilitating the arrangement of the type, as well as for type founding. In the Report on Printing, &c., of the Paris Exhibition of 1855, Mr. Knight says:—"During the last twenty years there have been various attempts to produce a machine that will, to some extent, supersede that portion of manual labour in printing which is called 'composition.' Without attempting to describe the various contrivances by which a more rapid method of arranging moveable types was to be effected than by the ordinary method, it may be sufficient to say that by keys, like those of a pianoforte, some force might be applied to remove a single letter from its proper receptacle, and arrange it in a combination of words and sentences. . . . There were several composing and distributing machines in the French Exhibition, but the most remarkable one, and that which appears to me, as it appeared to M. Didot and other competent judges, to approach nearer than any other invention to the accomplishing of this long sought for object, is thus entitled—'Machine à composer et mettre bas pour l'usage de l'imprimerie, composée et executée par Christian Sörensen.' It was stated that a Copenhagen newspaper, of which a copy was shown, had been printed for some time by this method. It would be impossible to convey an adequate notion of the details of this machine without drawings. I will endeavour briefly to state the principle:—The types are of the usual thickness and height. In the centre of each type, in the front, is a deep nick of a dovetail shape, which fits upon a metal edge, so that the type cannot be displaced. But of 111 letters which are required in the fount, each letter has two, three, or four nicks cut at right angles, the nicks of no one letter being the same as another. A cylinder, which may be described as a large basin, has a number of metal edges placed vertically in its sides, upon which the types without any regard to order, being the matter for distribution, are rapidly slid by the dovetail nick.

"When the basin is filled, it is inverted upon a cylinder of corresponding size below. Upon the rim of this cylinder is a separate opening for the reception of each of the 111 letters, but no one opening is like another. The distributing and the composing go on at the same time. The compositor is seated; with a treddle he moves the upper cylinder, which, as it slowly revolves, finds in the lower cylinder, which is stationary, a fit place for every separate letter as it descends by its own gravity to the bottom of each metal edge. The *n* having two broad nicks, one about ⅛ of an inch from its top, the other at the same distance from its bottom, falls into the *n* opening, which, having points corresponding, alone can admit it from its similarity of form, while the *u* having four nicks, two broad and two narrow, passes into its own division, and cannot be confused with the *n*.

"But whilst this process of distribution is steadily proceeding, without any care but to keep the upper cylinder occasionally supplied with new material for its operation, the process of composition is rapidly going on. The compositor sits before a compact little frame of keys, each key having a connecting wire for each division of the lower cylinder. He strikes a key and the lower letter is instantly detached and falls into a funnel-shaped receptacle below, where, without being inverted in any way, it runs into a groove, and arranges itself in its proper order, in the line of its fellows. This is a long line of several feet. By an ingenious contrivance each such line is passed on one side, as it is completed, to another workman, who takes up as many letters as will fill the due width of his page or column, and spaces out the words in the ordinary way. I saw 1000 letters thus placed in line in the short space of four minutes, and the spelling and punctuation appeared as correct as in most matter of common composition before it is read. When the necessary loss of time in refilling the cylinders, and through other hindrances, is taken into account, it was stated by the exhibitor that 50,000 types are set up and distributed each day. This gives a rate of about 6000 an hour, which is treble that of the ordinary compositor's rate."

Other machines, designed to attain greater rapidity, or of more simple and cheaper construction, have been produced since that exhibition; and a few have been brought into actual work in printing-offices, but without sufficient success to insure their general adoption. Among the latest of these inventions is that of Mr. Young, in which the keyed arrangement is adopted, the receptacle being filled as described above. The action of the lever knocks aside the letter required, which instantly drops into a special groove running down an inclined plane; and this leads to the general issue, where it is propelled by the action of a lathe, at the end of which it arranges itself in its desired order in an upright position, and is thus passed to a frame of divided spaces to admit the arranged types in long lines. As one space fills, a lever lifts it a line, until the whole is filled, when its place is supplied by an empty one. The frame thus filled is removed to the justifying machine. Here the frame is placed so as to bring the uppermost line on a level with an instrument brought by a screw to the width of the line required. The justifier glances his eye along the line, corrects any error that he detects, and slides as much as the line of the justifying machine will take with regard to the end or division of a word, and then spaces it tight. The instrument then drops a line, and the process is repeated till a page is formed, which is then removed. It is stated that one player will compose 13,000 letters per hour, and that this will occupy three compositors in justifying. Working nine hours a day, this would be 117,000 letters for four compositors, or about 29,000 for each; while at the common case they could not produce more than 18,000 at most by the usual process, which however includes the distribution, which must with this machine be effected by a compositor, although the inventor has in hand (Nov. 1860) a machine for performing the distribution also. When distributed, each type has to be set up separately, in order to be placed in their receptacles, and this is done by boys, at about the same rate as is done in *Type-founding*.

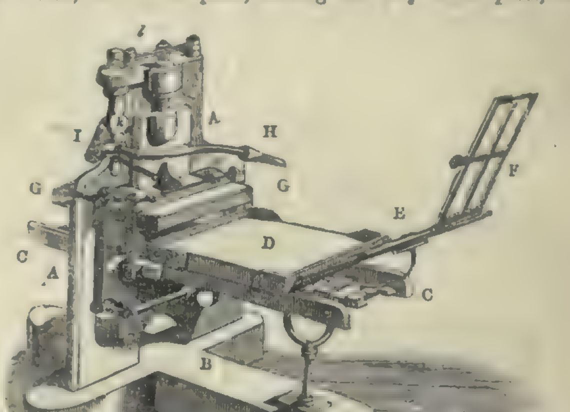
There is one drawback to all such machines, that appears almost impossible to overcome, and will greatly prevent their general use. They may arrange types with a rapidity far greater than is attainable by man's fingers in lifting them; but the superiority of machinery consists mainly in its being continuous. If this fails, the advantage is lost, and the interruptions are costly. Now in composing no one can move his fingers, either on the keys of a machine or into the boxes of a case, faster than he can read the copy. Few know better than a compositor the difficulty there is in reading most manuscripts. Even the change of a hand-writing is often an obstacle, and of many authors the writing is so peculiar or so bad as to take considerable time to decipher; and many others neglect the punctuation, which a good compositor ought carefully to attend to. On newspapers the copy is often from a copying-press, and is faint or obscure, or is written on thin paper with a pencil, with like defects. Nor is there any provision for the use of a word in italic, or in any different alphabet, such as Greek or Hebrew. Thus, in manuscript works, the worker at a composing machine would necessarily lose so much time in reading his copy as greatly to reduce his rate of speed; for if he mistake, the fault has to be corrected. This cannot be done by machine, and the correction frequently takes as much time as the original composition. With mere reprints they may answer better; but even with them we believe the idea of employing the cheap labour of boys has been given up, and it is found more remunerative to engage men already acquainted with their business as compositors.

Printing-press.—The term printing-press is applied to the machine used for letter-press printing, lithographic printing, or copper-plate printing, but more usually the first named, the others being called rolling-presses. The date of the invention of the printing-press is unknown, but some contrivance for this purpose must have been used as soon as printing by blocks or types was introduced. The increased force requisite to make an impression, the size of the surface to be printed from being increased, would soon suggest recourse to some of the simple machines or mechanical powers for the modification of the power requisite to obtain the necessary pressure. The screw, as applied in the common screw-press, would obviously suggest itself; and accordingly, in all the earlier printing-presses, the screw alone is used.

The operations to be performed in the process of printing will point out the essential parts of a printing-press. The types, being set up and arranged in a form of suitable dimensions, have to be inked; this is effected by passing across them a cylinder, or roller, covered with an elastic composition of molasses, glue, and tar. The paper to be printed has to be laid on the types when inked, and then the requisite pressure for making the impression has to be applied.

The earliest form of printing-press very closely resembled the common screw-press, as the cheese or napkin press, with some contrivance for running the form of types, when inked, under the pressure, and back again when the impression was made. This rude and inconvenient form of press was superseded by the invention of Blew, a printer of Amsterdam. Other improvements were from time to time introduced; but they were all superseded, about the commencement of the present century, by an invention of Lord Stanhope.

In the accompanying diagram of the Stanhope press, A is a massive frame of iron, cast in one piece, forming the body of the press, and firmly fixed to the cross B, or wooden foundation. The table C carries the form of types D, which, being placed on a carriage, traverses the table backwards and forwards, motion being given to it by means of the crank-handle acting underneath the table. To the carriage are attached the tympans E, which are light frames covered with parchment, and so constructed that the inner tympan just lies within the outer tympan. Some blanketing is placed between the tympans, so as to equalise the pressure upon the surface of the types. To the outer tympan is attached the frisket F. The sheet of paper to be printed being placed on the tympans, the frisket is turned down upon it; and then the frisket and tympans are turned down upon the form of types. The frisket is covered with paper or parchment, cut out so that the sheet to be printed, when placed between the tympans and frisket, and folded down together on the form of types, may be in contact with the surface of the types; while the remainder of the frisket-sheet preserves the margin from being soiled.



The form of types being inked, and the tympans and frisket, with the sheet of paper between them, folded down on the form, the whole is run, by turning the crank-handle, under the platen G, which is a massive plate of cast-iron, moveable up and down perpendicularly, its weight being rather more than counterbalanced by the weight I at the back. The pressman pulls the handle of the bar H towards him, or across the press, and thus communicates motion to *k* and *l*, and causes the spindle m, which sustains the platen, to descend and produce the requisite pressure. The principal improvement of the Stanhope press consists in the manner in which the descending motion is given to the screw. This depends on the properties of the bent lever, and may be explained in the following manner:—It is a necessary consequence of the peculiar combination and arrangement of the bent lever here employed, that on the handle H being moved, the platen descends rapidly at first; but as the platen comes very near to the extreme point of its descent. the motion is extremely slow. But at this instant the platen is pressing the paper upon the types, and the pressure exerted being inversely as the rate of the descent of the platen, whose motion at this instant is exceedingly slow, the pressure produced is enormously large. It will be found also that at the instant the platen is at its lowest point, the connecting bar *l*, by which the power applied is transmitted to the platen, passes across the centres of motion of the system of forces; at this instant, as theory points out, the ratio of the pressure produced to the power applied is indefinitely large. The pull having been made, or the pressure produced, the handle H returns to its original position, being taken back by the weight I at the back, which rather more than counterbalances the platen. The carriage is then run back, the frisket and tympans unfolded, and the printed sheet being taken out, the same operation is repeated. The usual rate of printing by the Stanhope press is two hundred and fifty per hour, two men being employed, one to ink the types, and the other as pressman.

The principle of the Stanhope press has been followed out by several subsequent inventors, and improvements of mechanical detail introduced, tending to the economy of time and labour, and to precision of workmanship. In the Ruthven press, the form of types remains stationary, and the plattin is removed to permit the types to be inked; and in this, as well as the Columbian, the pressure is produced by a combination of levers alone, without the use of any portion of a screw or inclined plane.

The press for copper-plate printing consists of two cylinders, or rollers, of wood, supported in a strong wooden frame, and moveable about their axes, one placed just above and another just below the level of the table upon which the plate to be printed is laid. The upper roller is turned round by the arms of a cross fixed to its axis. The copper-plate being inked, the paper on which the impression is to be taken, and two or three folds of soft material, as blanketing, are placed upon it. The plate so prepared is moved along the table to the juncture of the two rollers, and the upper roller being turned by the arms of the cross, the plate, with its furniture, is passed through the press. The rollers may be placed nearer to or farther from each other, according to the amount of pressure requisite for making a good impression, that is, according to the depth of the engraving and the degree of blackness which the impression is required to have. With slight modification the same form is used for lithographic printing, to which steam-power has been recently applied very effectively.

Printing-Machine.—The printing-press, though much improved during the last half-century by the ingenuity of Lord Stanhope and others, is quite inadequate to a rate of production equal to the present demand. The attention of practical men was consequently directed to some more rapid means of production, and as early as 1790, even before the Stanhope-press was generally known, Mr. W. Nicholson had letters-patent for a machine similar in many respects to those which have now come into use. Subsequently Mr. König, a German, conceived nearly the same idea, and meeting with the encouragement in this country which he failed to obtain on the Continent, constructed a printing-machine, and on the 28th of November, 1814, the readers of the 'Times' were informed that they were then for the first time reading a newspaper printed by machinery driven by steam-power. This printing-machine, though highly ingenious, was very complicated, and the machine of König was soon superseded by that of Messrs. Applegath and Cowper, the novel features of which were accuracy in the register, the method of inking the types, and great simplicity in hitherto very complicated parts. Printing-machines may be distinguished into single and double; the single being that in which only one side of the sheet of paper is printed, the double that in which both sides are printed before the sheet leaves the machine. The former is used for newspapers and that kind of printing in which it is not necessary for the two sides of the sheet to "register," that is, for the printing on one side to be exactly at the back of the other; the latter for books, in which it is essential that the printing on one page should correspond with the printing on the other when the sheets are folded. This important object of the register is effected by causing the parts to move at precisely the same speed. This being the principle of the register, its success will depend on great accuracy of workmanship in the mechanical parts. The accompanying representation of the printing-machine will furnish a correct notion of the several parts, and of the way in which motion is communicated to them. A sheet of paper is taken from the pile to be printed (as represented at the left-hand side of the drawing), and put into the machine by one attendant, and taken out printed on both sides by the other attendant, whose hand is shown under the cylinders. The accompanying sketch will show the principle of the printing-machine.

The sheet of paper taken from the table A is laid on the feeder B, which consists of girths of linen, tightly stretched by being passed round two cylinders. By the motion of this feeder the sheet is placed between the two systems of tapes which lie on the cylinder G: these tapes, of which one set is represented by the dotted line, and the other by the thin line, lie two and two over each other on the cylinders and small rollers *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*. The sheet of paper grasped between them is kept clean at the places in which it is in contact with them, and by the motion of the various parts is conducted under the first printing-cylinder H, and receives an impression from the types at C; thence by means of the cylinders I, K, to the second printing-cylinder L, where it receives an impression on the other side from the types at D. Thus printed on both sides, it is taken out at *e* by the attendant. The cylinders I and K are simply for the purpose of conveying the sheet steadily and smoothly from one printing-cylinder to the other. The sheet will be seen to be reversed in its progress from one set of types to the other, descending the left side of the first and the right side of the second printing-cylinder.

An inking-apparatus is placed at each end of the table M, N, which carries the types C, D, and which traverses backwards and forwards under the printing-cylinders L, H, and inking-rollers. The ink, received from a reservoir *k* by the two rollers *l* and *m*, is transferred from them to the surface of the table; the surface of the table inks the rollers *n*, *o*, and these, in their turn, ink the types as they pass backwards and forwards for each impression. The excellence of the printing depends in a great measure on the types being properly inked. In a machine arranged according to the accompanying diagram, the types are touched four times by the inking-rollers for each impression, and by increasing the number of rollers, any perfection of inking may be obtained. The machines commonly used for printing books will print from seven hundred to one thousand per hour, in perfect register; and for newspapers printed on one side only, from four thousand to six thousand per hour.

Steam-power has also been applied to flat machines, which are a modification of the Stanhope press, in which the table, with a form of type at each end, moves backwards and forwards under the platen, which gives the impression to one form while the other is being inked by the rollers. This description of press was for a time supposed to be best adapted for the finer sorts of book-work; but the process was very much slower, and the belief in their superiority of work was not universally admitted. Cylindrical machines were frequently used, not only for newspapers, where rapidity of production was required, but for books containing engravings on wood, where excellence of workmanship was demanded. Several of these machines were exhibited at the Paris Universal Exhibition in 1855, the French printers having devoted much attention to the improvement of cylindrical machines. In his report as juryman on 'Class XXVI.—Drawing and Modelling, Letter-press and Copper-plate Printing, and Photography,' Mr. Charles Knight says, "In the Paris Exhibition, several machines, offering the advantage of more perfect inking, and of preventing what is called 'setting-off' [that is, the sheet becoming blurred by the moist ink being pressed upon], showed that the attention of the French printers had been more directed than with us to the practicability of producing the finest work by the machine instead of by the hand-press. Some of our artists, who have watched the dependence of the wood-engraver on the printer, have long been of opinion that the equal operation of the cylinder is superior to the irregular force of the hand-press. But the heads of our printing establishments have generally considered that the cylindrical machine was only calculated to save labour, and not to produce fine work. Our machine-makers have, therefore, made various labour-saving machines upon the principle of flat pressure, which, as it is the principle of the hand-press, at which the most expensive work was produced, was thought to be the only principle for a more perfect machine. The French, on the contrary, have turned their attention to the perfection of the cylindrical machine, knowing that it had natural advantages which could not be obtained by flat pressure. When a sheet of paper is brought into contact with an inked surface of types, by being laid flat upon that surface, a large body of air has to be expelled by the heavy platen, operating at once upon the whole surface. The cylinder, on the contrary, touches the type, and produces the impression on the paper, line by line, and there is no atmospheric resistance to be overcome. The French printers have, therefore, sought for the improvement of the cylindrical machine. The single-cylinder machine of M. Dutartre produces work which cannot be excelled by the most careful operations of the press. It prints only on one side [the process having to be repeated to 'perfect' the sheet]; and the form passes under a double set of inking-rollers, at each end of the table, before it receives the impression. In the double-cylinder machine of the same inventor, a waste sheet of paper is interposed so as to prevent setting-off; and thus both sides of the paper may be printed at once, without leaving that blurred impression of one side which so commonly disfigures machine-printing. The French printers now do their finest work by the cylindrical machine, and much of their common work by the hand-press." The report goes on to say that, on

the whole, the average work of the French printers is superior to that of the English. It attributes this partly to the better quality of their paper, which is farther improved by being passed through powerful rollers, thus creating a more even surface, partly by using dry paper instead of wet, partly by the use of silk instead of parchment for tympans in their hand-presses and flat-pressure machines; and other little niceties, the results of long practice based upon scientific investigation. M. Dutartre's double-cylinder machine has been introduced into England; and a patent has been taken out for an improvement in the manufacture of paper, by which the necessity of wetting it to enable it to receive the ink will be removed: we believe, as far as this experiment has been carried out, that it has been successful.

M. Dutartre also exhibited a machine for printing in two colours, for which he received the silver medal. Others were exhibited for printing newspapers; but their rapidity was not equal to ours, as it appears from the report, 6000 sheets perfect being the highest number stated; but several ingenious adaptations and movements are noticed in Mr. Fairbairn's report.

In England, however, the demands of the newspaper press had not been met by even such improved machines as above described. The 'Times' could not be produced sufficiently early at the rate of 5000 or 6000 an hour. Mr. Applegath again employed his inventive faculty, and produced a printing-machine on the vertical cylindrical system, which could produce on one side from 10,000 to 13,000 copies an hour. With such machines the 'Times' has been worked since 1848; and the machine has been used for the production of the 'London Illustrated News,' and other newspapers having a large circulation.

In this machine a central drum 200 inches in circumference, or 64 inches in diameter, turns on a vertical axis. We copy the following description from C. Tomlinson's 'Cyclopædia of Useful Arts and Manufactures':—"The inking-table and the columns of type are secured to the surface of this drum; the columns of type are placed vertically, not conforming to the curve of the drum. This is contrived in the following manner. A slab of iron is curved on its under side, so as to fit the large cylinder, while its upper surface is fitted into facets, or flat parts, corresponding in width and number to the width and number of the columns of the newspaper. Between each column there is a strip of steel, with a thin edge, to print the 'rule,' the body of this strip being wedge-shaped, so as to fill up the angular space left between the columns of the type, and to press the type together sideways, or in the direction of the lines; the type is pressed together in the other direction by means of screws, and is firmly held together. The surface of the type thus forms a portion of a polygon, as already noticed; and the regularity of the impression is obtained by pasting slips of paper on the paper cylinder. The large central drum is surrounded by eight cylinders, each about 13 inches in diameter, also with vertical axes. They are covered with cloth, and upon them the paper to be printed is carried by means of tapes. Each of these cylinders is so connected with the central drum, by means of toothed wheels, that the surface of each must move with the same velocity as the surface of the drum. It will thus be evident that if the type on the drum be inked, and each of the cylinders be properly supplied with a sheet of paper, a single revolution of the drum will cause the eight cylinders to revolve also, and produce an impression on one side of each of the sheets of paper. But for this purpose it is necessary that the type be inked eight times during one revolution of the drum. This is accomplished by means of eight sets of inking-rollers—one for each paper-cylinder. The ink is held in a vertical reservoir (supplied from above), formed of a ductor-roller, against which rests the two straight edges connected at the back, so as to prevent the ink running out. It is conveyed from the ductor-roller by one of the inking-rollers in the following manner:—As the inking-table on the revolving drum passes the ductor-roller, it receives from it a coating of ink, and then coming immediately in contact with the inking-rollers, it inks them; the types next follow and receive from the inking-rollers their coating of ink; and the drum, still revolving, brings the inked type into contact with the paper-cylinders, and the sheet is printed. It must not be forgotten, as one of the distinguishing features of this machine, that the various processes which have just been enumerated for one set of inking-rollers and one paper-cylinder are repeated eight times for every single revolution of the central drum, so that in this period eight sheets are printed and turned out of the machine. For this purpose it is necessary to supply the eight cylinders each with a sheet of paper. Over each cylinder is a sloping desk, upon which a number of sheets of white paper are placed. The layer-on stands by the side of this desk, and pushes forward the paper a sheet at a time toward the tape-fingers of the machine. These tapes seize it and draw it down in a vertical direction, between tapes, in the eight vertical frames, until its vertical edges correspond with the position of the form of type on the drum. When in this position its vertical motion is arrested for a moment; it then moves horizontally, and is carried towards the printing cylinder by the tapes. Passing round this cylinder, it is instantly printed. It is then conveyed horizontally, by means of tapes, to the other side of the frame, and is moved along to another desk, where the taker-off pulls it down. As soon as the sheet is thus disposed of, accommodation is made for another; and as each layer-on delivers to the machine two sheets every five seconds, sixteen sheets are thus printed in that brief space; and this is continued for any length of time, supposing no accident occurs, such as a sheet going wrong, in which case it is the duty of the taker-off to pull a bell-handle, and the machine is instantly stopped by the engine-man. As the type-form on the central drum moves at the rate of 70 inches per second, and the paper to be printed moves at the same rate, if by any error in the delivery and motion of a sheet of paper it arrive at the printing cylinder 1-70th of a second too soon or too late, the relative position of the columns on one side as compared with those on the other side of the paper will be out of register by 1-70th of 70 inches,—namely, one inch,—in which case the edge of the printed matter on one side will be an inch nearer to the edge of the paper than on the other side. . . . . . . All the layer-on has to do is to draw forward the sheets so as always to have the edge of one ready for the machine to take in. If the steam-engine which works the machine be put on a greater speed, the central drum, and all the attendant apparatus, would work with greater rapidity; and such a speed might easily be obtained as to render it impossible for the layers-on to present the paper fast enough to satisfy the improved appetite of the machine; but in any case the machine would not take in the sheets *as* the layers-on choose to present them, but only at those periods, rapidly recurring though they be, which are provided by the peculiar functions of the machine."

Another machine, likewise on the vertical principle, has been invented by the Messrs. Hoe, of America, and several of these have been brought into use in London.

Stereotyping.—The art of stereotype printing is the printing from cast plates of type-metal in lieu of moveable letters or types, and derives its name from the Greek *στερεός*, firm or fixed, and *τύπος*, a figure or type. This art is a remarkable illustration of the tendency of some inventions to return, after a long course of improvement, very near to their original simplicity. In the commencement of the art of printing, solid blocks of wood were used, containing, in one piece, all the words of which a page was composed. A great improvement upon this plan was the use of single letters or types, which might be combined into words and pages, and, after being printed from, might be distributed and re-arranged for another work. Then followed the process of type-founding, or casting the letters individually in moulds, by which they might be multiplied with facility, and being engraved originally upon steel punches, might be executed with greater neatness. Whether the early printers employed logotypes, that is, types for printing whole syllables or words, to any material extent, is not very certain; but it is well known that many persons have proposed, since the introduction of moveable types, the use of such logotypes for the purpose of facilitating the operation of printing; while others have adopted processes which approach more nearly to the old plan of printing from page-blocks, either by fusing the types composing a page into a solid mass, or, as in the modern art of stereotyping, by taking a mould from the page or *form* of moveable types, and using it as the matrix in which to make a solid cast or plate of metal. The face of such a cast is a fac-simile of the types from which the mould is taken, and may be printed from in the same manner as the original form or page.

Many of the accounts of the various projects which bear an affinity to the art of stereotyping, as practised by modern printers, are very indistinct; and the claims of some of the projectors are exceedingly perplexing. Those readers who desire minute information may consult works which enter at length into the history of printing, and especially a very interesting 'Essay on the Origin and Progress of Stereotype Printing,' published in 1820, by Mr. Hodgson, of Newcastle. The subject is also treated at considerable length in Hansard's 'Typographia;' but much of the history contained in that work is derived from the volume before mentioned.

One of the earliest schemes which claims notice in this brief sketch is that which was tried at the beginning of the last century by a Dutchman named Van der Mey. The booksellers Luchtmans, of Leyden, in a letter dated 1801, which was printed by M. Camus, in his 'Histoire et Procédés du Polytypage et de la Stéréotypie,' described some plates or blocks formed by Van der Mey, which had been used in their establishment ever since 1711. These were the forms for a quarto Bible; but a few other works were executed in the same way. They were not cast solid, but consisted of ordinary types, which, after being set up in the usual way, were converted into a solid mass by soldering them together at the back. The great expense of forms prepared in this way, as well as their inconvenient weight and bulk, is quite sufficient to account for the plan having fallen into disuse. It was indeed only applicable in those very rare cases in which it was desirable, in order to meet a constant demand, to keep the forms of type standing; and was preferable to that practice only inasmuch as it avoided the risk of some of the letters being accidentally loosened and misplaced.

William Ged, a goldsmith of Edinburgh, if not absolutely the first, was one of the first to practise stereotyping, according to the common acceptation of the word. His claim to this honour is recorded in a rare pamphlet published by Nichols in 1781, and reprinted in 1819 by Hodgson of Newcastle, entitled 'Biographical Memoirs of William Ged, including a particular account of his progress in the art of Block-printing.' From this work it appears that Ged invented a process for casting whole pages about the year 1725, and that a few years afterwards he and others who were associated with him attempted to apply his invention to the production of bibles and prayer-books for the university of Cambridge. One of the difficulties to be encountered in the introduction of this innovation was the prejudice and opposition of the compositors, who, by the artful production of errors in the forms of type, rendered the casts so incorrect as to bring them into discredit. The scheme was abandoned by the University, and most of the plates were destroyed. A battered and otherwise imperfect specimen, which escaped the melting-pot, is printed in Hansard's 'Typographia.' Ged cast plates for a few other works, one of which was an edition of Sallust, in 18mo, which, according to his son and daughter, was executed in 1736, though Hodgson says that he never saw a copy dated earlier than 1739, and that the edition commonly bears the date 1744. In Hodgson's Essay a page of this work is reprinted, which is a far better specimen of stereotyping than that given by Hansard. This plate, which had been previously printed in the tenth volume of the 'Philosophical Magazine,' is about a quarter of an inch thick.

About the year 1780, Mr. Tilloch, editor of the 'Philosophical Magazine,' conceived the possibility of founding whole pages; he being at that time unacquainted with the prior experiments of Ged. He communicated his idea to Foulis, printer to the university of Glasgow; and they jointly produced several works; some of which were circulated without any intimation of the process by which they were printed. Hodgson gives very good specimens of their work. Finding some inconvenience in the use of blocks of wood for mounting the plates, in order to raise them to the same height as type, these experimentalists tried blocks of brass, having slits through which small screws might pass to secure the stereotype plates; the screws being fastened by nuts on the under side of the brass mounts. In order to bed the plates as evenly as possible, whether the mount were of brass or wood, they interposed a layer of cement between the plate and the mount. In the latter case the thickness and level were adjusted by planing the back or under side of the wood; and in the former by warming the mount, and then placing it, with the plate, into a press, and squeezing out the superfluous cement. An account of the experiments of Tilloch and Foulis was published in the tenth volume of the 'Philosophical Magazine.' Satisfactory as they were, they did not immediately lead to the adoption of stereotype printing.

Towards the latter end of the 18th century, many projects were brought forward in France for multiplying engraved blocks or forms of type by processes more or less resembling that of stereotyping, under the names of polytype, stereotype, &c. In some of these, the form was imitated by striking upon a mass of soft metal in a state intermediate between perfect fusion and perfect solidity, on the principle of the process now practised in France under the name of *clichage*. The extensive issues of assignats by the revolutionary government gave an impulse to such schemes, of which many were devised, and some were brought into operation, in order to render the assignats more difficult of imitation. In 1798 a stereotype edition of Virgil was published by the Didots and M. Herman; and it appears from Hodgson that, before the close of the century, the wood-engravers of Paris sold metal casts of their wood-cuts.

Some of the early experiments of Senefelder, the inventor of lithography [SENEFELDER, in BIOG. DIV.], were directed to the discovery of a means of stereotyping by which he might be enabled to print his own works with a very small stock of type. He formed a composition of clay, fine sand, flour, and pulverised charcoal, mixed with a little water, and kneaded as stiff as possible; and with this paste he made a mould from a page of types, which became, in a quarter of an hour, so hard that he could take a very perfect cast from it in melted sealing-wax, by means of a hand-press. He states that, by mixing a little pulverised plaster of Paris with the sealing-wax, the stereotype plates thus produced were much harder than the common type-metal of lead and antimony. The want of pecuniary means for carrying on this project led him to abandon it, and to contrive a plan for printing from stone. Another ingenious proposal which may be here mentioned, is that of Professor Wilson, of Glasgow, who, in 1797, devised a method of multiplying engraved blocks or plates by stereotype, or rather polytype, impressions, in glass or enamel, which, it was anticipated, would prove very durable, and might be applied with advantage to the prevention of forgery. Hodgson gives specimens of two casts of small wood-cuts produced in this manner.

The revival and introduction into common use of the stereotyping process is, in a great measure, due to the exertions of Earl Stanhope, about the commencement of the present century. Mr. Tilloch communicated to him the result of his experiments, and Foulis, who, as before stated, had been associated with Tilloch, assisted in the trials made at his lordship's seat at Chevening, in Kent. Andrew Wilson also was connected with these operations, and exerted himself much to introduce the process. The latter individual, who received a gold medal from the Society of Arts in 1810, for his "great skill and exertions in stereotype printing," produced several important stereotyped works, of which Hodgson considers his edition of Walker's 'Pronouncing Dictionary,' executed in 1809, to be the best. A specimen of his work, which was printed in the 28th volume of the 'Transactions' of the Society of Arts (pp. 323-4), shows that he was then able to produce very good casting from type as small as Nonpareil and Pearl. In 1803 or 1804 the process which had been perfected at Chevening was communicated to the university of Cambridge, and shortly afterwards to that of Oxford; but the first work printed in this way at the former place did not appear until 1807, and 1809 is the date of the earliest stereotyped book issued at Oxford.

In setting-up a form intended for stereotyping from, the *spaces*, or short pieces of metal by which the words are separated from each other, and the *quadrats*, or larger spaces by which blank lines are filled up, are cast higher than usual. The types are set up and formed into pages in the usual manner, with the illustrative wood-cuts, if there be any; but, instead of these pages being arranged into a form of sufficient size to print a whole sheet, each page, if large, or every two or four pages, if small, is separately locked up in a small frame or *chase*; the pages being surrounded by fillets of wood or metal, which serve in the cast to form a border for attaching the plate to its mount. The face of the types is then moistened with oil, to prevent the mould from adhering to them. A brass frame, rather larger than the page, is laid upon the chase, in order to retain the plaster while in a fluid state, and to regulate the thickness of the mould. The plaster is then poured on the types, and it soon sets into a solid mass, which must be removed from the types with great care, and trimmed on the edges with a knife. The plaster moulds are, in the next place, baked in an oven heated to about 400° Fahr., until thoroughly dry and hard. They are placed upright in a rack, and are usually dried in about two hours. Great care is required in this process, especially when the moulds are large, to prevent them from warping.

After being baked, the mould is placed, with its face downwards, upon a smooth plate of iron, called a *floating-plate*, which lies at the bottom of a cast-iron box rather larger than the mould. The box is then covered in by a lid, the under surface of which is made perfectly flat, and which has the corners cut off, to allow the melted metal to enter the box. The cover is firmly held down by a screw, which is attached to an apparatus by which the box is suspended from a crane. It should be observed that the casting-box and plate are heated to the same temperature as the mould, before it is inserted. The box is then swung by the crane over the metal-pit, which is an open iron vessel containing a large quantity of melted metal, resembling in its composition that used for casting types; and it is lowered into the metal in a nearly horizontal position, being a very little inclined, to facilitate the escape of air from the mould and box. The melted metal runs in at the corners of the box; and, by its greater specific gravity, floats up the plate with the mould, forcing the latter tightly against the lid of the box. By this contrivance the metal is forced, by hydrostatic pressure, into every part of the mould, in the margin of which notches are cut to allow free passage for the metal between it and the floating-plate. After remaining immersed in the metal for about ten minutes, the box is gently raised, and removed by the crane to a trough in which its lower part is rapidly cooled by contact with cold water. While the box is cooling, the caster pours in a little metal at the corners, to fill the space left by the contraction of the metal, and so to keep up the necessary pressure upon the cast. When cold, the contents of the box are removed in a mass, from which the superfluous metal is broken off by blows from a mallet. The plaster mould is then broken away from the cast, the face of which is a facsimile of the types and engravings from which the mould was taken. As the mould is destroyed by this process, it is necessary, when several stereotype plates of the same page are required, to take a distinct plaster mould for each.

Another plan, which has been tried for the production of stereotype plates too large for casting in the ordinary way, but which has not proved very successful, is to place the mould in a flat iron box, having a trough-shaped mouth at one end, and to pour in the metal with the mould-box, which must be previously heated, in an inclined position. The method of striking the moulds, and from them the plates themselves, by letting the original or pattern types or blocks fall upon a mass of soft metal in a half melted state, is practised in France, and has been repeatedly tried in this country: it is especially adapted for the production of copies of wood engravings, but it is very liable to injure a delicately engraved block. In this, as in the ordinary casting process, the original engraved blocks should be smeared with some substance that may prevent the cast from adhering to them.

A process of stereotyping, which was several years in attaining its present practical efficiency, has been introduced from Paris. On receiving the type, moistened sheets of unsized tissue paper are laid over it, one above the other, to the number of six or seven, slightly pasted together, and upon these is laid a stouter paper; the whole is then struck with a large flat brush till the softened paper has received a perfect impression of the type. This being done, the paper is removed, placed upon a hot iron table, a blanket laid over it, and screwed down moderately tight, in order to harden it and extract the moisture. The whole operation (paper having been prepared by wetting a few hours in advance) occupies less than an hour. From this mould a stereotype cast can be taken by merely pouring in the molten metal on it when placed in a receptacle, in which a simple contrivance at once regulates the thickness and the size of the plate, that is, how much or how little margin is left outside the type for the purpose of fastening it to the blocks. A couple of hours suffices for the whole process; and it is now adopted upon several newspapers and other publications of large circulation, as many casts can be taken from one mould. A plurality of machines or presses are thus enabled to be set to work for the production of the requisite supply.

Another considerable advantage is, that the moulds may be preserved, so as to be used whenever wanted. It is only necessary that they should be stored so as to be neither too warm, nor too damp, nor too dry, as the paste will ferment, or the sheets crack and separate. With care however they may be kept safe for a considerable time, and thus the locking up of a large amount of metal may be avoided.

The alloys used for various kinds of stereotyping differ slightly in their composition, but generally consist of type metal.

Stereotype-plates need careful examination and *picking*, to remove the imperfections in the casting. Small hollows, such as the loops of an a, an e, or an o, are liable to be filled up with metal, owing to blebs of air in the mould, and the fine white lines in wood-engravings are sometimes filled up. Such matters should be corrected by the picker, who should also cut down, with suitable tools, such blank spaces as might be liable to soil in printing. Before printing, also, defective letters or words which cannot be corrected by the picker should be cut away, and types inserted in their place. These types are soldered into holes drilled through the plate; their stems being sawn off flush with the back.

Although the plates are cast of as equal a thickness as possible, they require, before printing from, to be accurately flattened at the back by means of a peculiar kind of lathe, in which a steel cutter, or *knife*, mounted in a slide-rest, shaves off the metal from the back of the plate in concentric circles, until it is made perfectly even. They are then mounted upon blocks of wood or metal, to raise them to the same height as common types. The tendency of wood to warp when exposed to changes of temperature, or to occasional wetting, has led to many projects for mounting stereotype-plates upon blocks of cement, or upon metallic mounts which might be applicable to plates of various sizes. When wooden blocks are used, the plates are usually secured to them by clips at the edges, and sometimes by screws.

The process of stereotyping is one of the most important means by which the production of cheap books has been facilitated of late years. For a work of limited and temporary demand it is unnecessary; but where the demand is very great, and likely to last for several years, it is all-important, since it enables the publisher to keep up the supply without the expense of having a very large edition printed at once. In most cases where the demand is uncertain, and in almost all where the demand is sure to be large, it is desirable to resort to stereotyping, because, although it increases the first cost of production, it enables the publisher to avoid, on the one hand, the risk of printing a great number of copies which may prove unsaleable, and, on the other, the outlay necessary for the re-composition of the types, in case the demand should exceed the number of copies first printed.

It has often been urged as an objection to stereotype printing that it tends to perpetuate errors; but the fallacy of such a statement may be easily shown. In re-composition new typographical errors are pretty sure to arise, while the expurgation of old ones is by no means certain; but in stereotype plates the occurrence of new errors (excepting by the breaking off of a letter or figure) is impossible, and original errors may be altered whenever they are discovered. Such alterations are not necessarily confined to the insertion of a letter or a word; for whole sentences and paragraphs may be altered in like way, provided that the new matter be made the same in extent as that which is cut away. Hence a stereotyped work may be gradually rendered almost immaculate; and an error which would otherwise have run through the whole edition, may be corrected when only a few hundred copies have been circulated.

The interest connected with the question of *Printing for the Blind*, to which considerable impetus was given by the Society of Arts for Scotland at Edinburgh, who offered their gold medal for the best alphabet for the blind, has tended greatly to bring about a change in the intellectual education of the blind. The publication of the article BLIND in the 'Penny Cyclopædia' at a time when the minds of many were thus directed, and the strictures therein contained on the absence of intellectual training in most of the asylums, also rendered essential benefits on this point. Dr. S. G. Howe, of Boston in the United States, in 1833 contrived an alphabet, founded upon that of Haüy, of a very compact form, in which the New Testament was printed in 1834, and is now in general use in America. The late Mr. John Alston, the treasurer of the Glasgow Asylum, than whom no man connected with the blind deserves more honourable mention, contributed greatly to this educational movement. He saw that, by adopting any character more or less arbitrary, the evil would necessarily follow of isolating the blind by putting them in a position to require special teachers. He therefore adopted the plain Roman characters deprived of their small extremities—the *sans-serif* of type-founders; and, finding that it could be easily read, that it would enable any seeing person who could read to be a teacher of the blind, he at once procured founts of type, and published several works in raised letters; the success of these for their special object established the pre-eminence of his alphabet. Having thus laboured for several years, he visited more than once the principal asylums for the blind in the kingdom. In his work 'Statements,' &c., published in 1846, he says, that after the introduction of his system, "I found a considerable improvement. Subsequently I visited the English institutions a third time, and found a very great number who could read with ease and intelligence; and I have reason to know that there are some hundreds reading these books, and that many families are in possession of the whole of the Bible in raised types: thus in a short time showing the sufficiency of the system placed before the public." It may be added, that Mr. Alston also brought out some beautiful music and maps, and that he published the Old and New Testament in 19 vols., super-royal 4to. The paper used for these works is strongly sized, to retain the impression. In order to account for the great extent of the Bible, it must be borne in mind that the paper can only be printed on one side, and that the letters require to be of considerable size in order to be distinct to the touch. The printing is effected by a copper-plate press. The types being strongly relieved, and liable frequently to give way under the heavy pressure required, it was necessary to have them re-cast four times during the progress of the work. The whole of the works were completed within the walls of the Glasgow Asylum, a man and a boy acting as compositors, there being one pressman, and the ordinary teacher acting as corrector of the press. These books are now used in most of the British asylums for the blind, and also in America. The success which has attended Mr. Alston's exertions was a new assurance to the Society of Arts for Scotland that they had acted wisely in regarding the stenographic and all other arbitrary characters, as well as the angular modifications of the Roman alphabets, unfavourably.

Nature-printing, also called *Autotypography*, is an invention introduced from the Imperial printing-office in Vienna, by the late Mr. Henry Bradbury. The merit of the discovery has been a matter of contest into which we shall not enter, but we may remark that M. WORRING (in BIOG. DIV.), to whom we have attributed much of it, has disclaimed all beyond carrying into effect the suggestions of Councillor Auer, the director of the Imperial printing-office. The invention successfully pretends to give an exact reproduction of natural objects, such as plants, the grain of wood, &c.; and of other flat substances, such as lace, &c., in a form which enables a large number of impressions to be printed, and in their natural colours. The transference of the forms of plants to paper had been effected even centuries since, either by staining the plants, or by simple pressure. In this manner, however, the object, after taking a few impressions, was rendered useless. At Vienna the art was rendered more perfect by taking an impression on polished lead, from which impressions could be printed, though still in only a very limited number. Softened copper-plates were then adopted, which were found equally capable of receiving the impression, to its minutest markings, of the substance pressed on it. The object is arranged on the plate in the desired form, and is then subjected to an enormous pressure for a sufficient time, when it is found that the object has left its form deeply impressed upon the plate. This plate is subsequently hardened, and is fitted to furnish a large number of impressions. The plates are coloured, or inked as it is termed, with the proper colours of the plant, which is easily done, as the face of the plate is wiped after each colour has been laid on; the paper is laid upon the plate and passed through a press formed of two cylinders pressing against each other, of which one is covered with thick blanketing, and with a regulated pressure, the impression is produced in a low relief. In Vienna, several works of a magnificent character have been produced. In England there have been three, 'The Ferns of Great Britain;' 'British Sea Weeds;' and 'Trees of Great Britain;' all of which possess a high degree of excellence as works of art, and are of course of unexceptionable correctness.

Electro-printing.—The processes of the "Electro Printing-Block Company" (patented by Mr. H. G. Collins) supply the means of reproducing drawings, engravings, &c., without the aid of copyist or engraver, not only of the same size as the original, but enlarged or reduced with strict accuracy to any extent that may be desired. Thus, from a woodcut or steel engraving, say of 6 inches by 4, a working plate or block can be produced that will yield impressions 12 inches by 8, or 3 inches by 2, or of any other required proportion. We will briefly describe the beautifully simple means by which this is effected, and then indicate a few of its actual or probable applications.

The whole, in fact, depends on the capacity of india-rubber for extension in any direction, and its property of returning to its original size when the tension is removed. Let us suppose that it is desired to obtain an *enlarged* copy of an engraving. The surface of a sheet of galvanised india-rubber, the size of the print, is covered with a film of an elastic composition, and upon this film, when dry, an impression of the print is taken by means of transfer ink. The sheet so printed upon is then placed in a rectangular steel frame, hooks from the sides of the frame passing through holes pierced at equal intervals in the edges of the india-rubber. By a simple but ingenious double screw action, two opposite sides of the frame are now gradually drawn apart, till it is seen, by a scale engraved on the sides, that the india-rubber sheet is sufficiently extended. The same is done with the other two sides; and the whole having been carefully examined to see that the enlargement is uniform, the frame is fixed, in order that the strained sheet may not be in any way disturbed during the next operation. The impression thus enlarged on the india-rubber is now transferred by the ordinary lithographic transfer process to a lithographic stone, or zinc plate, which, after the usual treatment [LITHOGRAPHY], yields impressions exactly like any other prepared lithographic stone.

For a *reduced* copy, the only difference in the process is, that an india-rubber sheet of the desired size is strained to the dimensions of the print to be copied, before the impression is placed upon it, and then allowed to contract to its original size, when the impression is transferred to the stone. It ought perhaps to be mentioned that first of all the india-rubber sheet has printed upon it thin lines, which divide its whole surface into squares of a quarter of an inch each, thus affording, by means of the T square and compasses, an easy means of detecting the slightest inequality of extension in any part during the process of enlarging, whilst the frame is so constructed as to permit any deviation to be at once remedied.

For obtaining blocks for *surface-printing*, an additional process is required. After the enlarged (or reduced) impression is transferred to the lithographic stone or zinc plate, the surface of the stone or zinc is exposed to the action of an acid, which eats away all the parts not protected by the ink. The print is thus left in raised lines corresponding to those of an engraved wood-block. A matrix is taken in some suitable material, and upon this a cast, corresponding to the original wood-block, or a stereotype from it, is formed by the ordinary method of electrotype deposit. [ELECTRO-METALLURGY.]

The processes we have described suffice for all the usual purposes of lithographic printing, and printing by the ordinary type-press. To both there are limitations within which only success can be at present assured. Mezzotint, or finely stippled plates, for instance, cannot be successfully reproduced; but ordinary steel plates, wood-cuts, music, maps, and plans, can be enlarged or reduced with minute accuracy, and printed as lithographs with perfect certainty. The surface-block is somewhat less certain; but very beautiful results have been obtained, and the manipulative difficulties appear in a fair way of being overcome.

The further applications of the process seem almost illimitable. For surveying and engineering purposes, for example, a sheet of the Ordnance map could be taken, and in a few hours a copy be produced large enough to admit of the insertion of any amount of local detail. For the potter's use, from a single small drawing or print of a pattern, copies to any extent may be produced, to suit the various sizes of all the articles of a tea- or dinner-service; and if the original pattern be circular, it may be altered to an oval for dishes, &c. Its application to various other branches of ornamental art and manufacture, where variations of the size or form of designs are required, is obvious: whilst in fine art, the small pen or pencil sketch of an artist may at once, by mere mechanical means, be reproduced as a good-sized lithograph; the original study of a painter, if he choose so to work, be enlarged ready to his hand on his canvas, preparatory to painting; the diagram of the man of science speedily be reproduced of a size suitable for the lecture-room. Another application which the process is said to be already quite capable of carrying into practice is, that of reproducing impressions (of course of any size required) of books or engravings, even though a couple of centuries may have elapsed since they were printed. And any of these applications of the method is obtainable at a comparatively small cost.

PRINTING, CALICO. [CALICO-PRINTING.]

PRIOR, PRIORY, ecclesiastical terms denoting certain monastic foundations and the heads of such foundations. They differ in nothing essentially from the terms abbot and abbey. There were in England religious houses the chiefs of which were called priors, quite as rich and as powerful as many that had a chief who was called the abbot. Thus in Yorkshire there were two houses at no great distance from each other, called Roche and Nostel, the head of the former being an abbot, and of the latter a prior, though Nostel was the more ancient and more considerable foundation. The prior of St. John of Jerusalem was equal to any abbot; yet in the main we find the greater monastic foundations presided over by monks who were called abbots. In some cases there was both an abbot and a prior, when the abbot was regarded as the superior officer; and in the priories there was often a second officer called the sub-prior.

PRIORITY. [NOTICE.]

PRISM (πρίσμα), in Mathematics, is a solid formed by a straight line which moves parallel to a given straight line, and one end of which traces out the contour of a given rectilinear polygon. The other extremity of the moving straight line traces out an equal and similar polygon, placed parallel to the former one: and the prism is thus bounded by two equal and parallel polygons, joined by as many parallelograms as each polygon has sides. When these parallelograms are at right angles to the planes of the polygons, the solid is called a right prism; in all other cases, an oblique prism. The prism is among plane solids what the cylinder is among curvilinear ones: it is also called triangular, quadrangular, pentagonal, &c., according as the polygons have three, four, five, &c., sides. Thus the prism used in optics is a triangular prism, while the parallelopiped is a quadrangular prism.

The number of cubic units in the contents of a prism is found by multiplying the number of square units in either of the polygons by the number of linear units in the perpendicular distance between the planes of the two polygons; and all prisms, however much they may differ in obliquity, which have equal bases, and equal heights or perpendicular distances between opposite polygons, are equal in magnitude.

No other rule can be given for computing the surface of a prism except the simple direction to add the areas of the two polygons to those of the joining parallelograms. But in the case of a right prism, the finding of the parallelograms may be shortened by multiplying the number of linear units in the contour of one polygon by the altitude of the prism.

PRISM. [OPTICS; REFRACTION.]

PRIVATE ACT. [PARLIAMENT.]

PRIVATEER, a private ship of war, fitted out at the cost of an individual for the purpose of carrying on hostilities on his own account, but under the sanction of a belligerent state, against the public enemy. It is the practice of most nations to commission vessels of this kind as auxiliaries to the public force. The owners of them are licensed to attack and plunder the enemy, and their enterprise is encouraged by allowing them a large portion of any property they may capture. By the law of nations they are not considered pirates. It is usual for the country on whose behalf they carry on war to take security for their duly respecting the rights of neutrals and allies, and observing generally the law of nations. [PRIZE.] (45 Geo. III. c. 72; 1 Kent's 'Commentaries,' 96.)

PRIVILEGE (*Privilegium*, from the sense of which however it has been perverted), a particular beneficial exemption from the general rules of law. Privilege is of two kinds; *real*, attaching to place, and *personal*, attaching to persons, as ambassadors, peers, members of parliament, attorneys, &c., whose peculiar privileges are stated under these heads respectively.

Formerly many places conferred the privilege of freedom from arrest, even in criminal matters, upon those entering them [SANCTUARY]; and even in later times many places existed which privileged those within them from arrest in civil suits. Of these the most notorious were White Fryars, the Savoy, the Mint, and other places in their neighbourhood. But by 8 & 9 Wm. III. c. 27, the privileges of all these places were abolished. However at the present time, no arrest can be made in the king's presence, nor within the verge of the palace of Westminster, nor in any palace where he resides, nor in any place where the king's justices are sitting. (3 'Inst.,' 141.) Personal privilege, conferring freedom from arrest, is enjoyed by all suitors, counsel, witnesses, or other persons attending any courts of record upon business, or an arbitrator under a rule of Nisi prius. This exemption is to be interpreted liberally, and will not therefore be forfeited by taking refreshment after a suit, or by going other than the direct road to or from a court. (Com., 'Dig.,' tit. Privileges.)

PRIVILE'GIUM. [LAW.]

PRIVY COUNCIL (Consilium regis privatum, concilium secretum et continuum concilium regis). The privy council, or council table, consists of the assembly of the queen's privy councillors for matters of state. Their number was anciently about twelve, but is now indefinitely increased. The present usage is, that no members attend the deliberations of the council who are not especially summoned for that purpose. They must be natural-born subjects of England, and are nominated by the crown without any patent or grant. After nomination and taking the oath of office, they immediately become privy councillors. Formerly they remained in office only during the life of the sovereign, who chose them subject to removal at his discretion; but by 6 Anne, c. 7, the privy council continues in existence six months after the demise of the crown, unless sooner determined by the successor, and they are to cause the successor to be proclaimed. The privy council of Scotland is now merged in that of England, by 6 Anne, c. 6. The duties of a privy councillor, as stated in the oath of office, are, to the best of his discretion truly and impartially to advise the king; to keep secret his counsel, to avoid corruption, to strengthen the king's council in all that by them is thought good for the king and his land, to withstand those who attempt the contrary, and to do all that a good councillor ought to do unto his sovereign lord. By the Act of Settlement (12 & 13 Wm. III. c. 2) all matters relating to the government properly cognizable in the privy council are to be transacted there; and all the resolutions taken thereon are to be signed by such of the privy council as advise and consent to them.

The court of privy council is of great antiquity; and during earlier periods of our history appears not always to have confined itself to the entertainment of mere matters of state. It had always and still has power to inquire into all offences against the government; but it often assumed the cognizance of questions merely affecting the property and liberties of individuals. This is evident from the complaints and remonstrances that so frequently occur in our history, and ultimately from the declaratory law of the 16 Chas. I. referring to such practices. Probably the very statement of Sir Edward Coke, that the subjects of their deliberation are the "publique good, and the honour, defence, safety, and profit of the realm . . . . private causes, lest they should hinder the publique, they leave to the justices of the king's courts of justice, and meddle not with them," proceeded from his knowledge that such limits had not always been observed, and his jealousy of their invasion. Several other passages in his works seem to show that this was so. The attempts to enlarge the jurisdiction of the council appear always to have been resisted as illegal; and they were finally checked by the 16 Chas. I. c. 10. That statute recites that of late years "the council-table hath assumed unto itself a power to intermeddle in civil causes, and matters only of private interest between party and party, and have adventured to determine of the estates and liberties of the subject, contrary to the laws of the land, and the rights and privileges of the subject." By the same statute it is declared and enacted that neither his majesty nor his privy council have or ought to have any jurisdiction in such matters, but that they ought to be tried and determined in the ordinary courts of justice, and by the ordinary courts of law.

Subsequently however to this statute, in matters arising out of the jurisdiction of the courts of the kingdom, as in colonial and admiralty causes, and also in other matters, where the appeal was to the king himself in council, the privy council continued to have cognisance, even though the questions related merely to the property of individuals. By 2 & 3 Wm. IV. c. 92, the powers of the high courts of delegates, both in ecclesiastical and maritime causes, were transferred to the king, in council. The decision of these matters being purely legal, it was found expedient to make some alterations in the court, for the purpose of better adapting it to the discharge of this branch of its duties. Instances had before occurred where the judges had been called in and had given extra-judicial opinions to the privy council; but the practice was inconvenient and unsatisfactory, and all necessity for it is now wholly removed. By the 3 & 4 Wm. IV. c. 41, the jurisdiction of the privy council is further enlarged, and there is constructed from it a body entitled "the judicial committee of the privy council," which now consists of the keeper of the great seal, the chief justices, the master of the rolls, the chief baron, and other great judicial officers. Power is also given to the king by his sign manual to appoint any two other persons who are privy councillors to be members of the committee. The same powers for enforcing their decrees, &c., are given to the judicial committee as are possessed by the Court of Chancery, Queen's Bench, &c.

The privileges of a privy councillor, beyond those of mere honorary precedence, formerly related to the security of his person. If any one struck another a blow in the house or presence of a privy councillor, he was fineable. Conspiracy by the king's menial servants against the life of a privy councillor was felony, though nothing were done upon it. And by 9 Anne, c. 16, any unlawful assault by any person on a privy councillor in the execution of his office was felony.

These statutes have however been now repealed, by 9 Geo. IV. c. 31, and any offence against a privy councillor stands on the same footing as offences against any other individual. (1 'Co. Lit.,' 110, a. n. 5; 3 'Inst.,' 182; 4 'Inst.,' 52; 1 'Blackst. Com.' Mr. Kerr's edit., ch. 5; Hallam's 'Constitutional History.')

PRIVY SEAL. [SIGN MANUAL.]

PRIZE, property taken from an enemy at sea, the law as to which is regulated by the general law of nations. As between the belligerent powers themselves, the property in a ship or other thing captured passes at once, by the mere taking itself, to the captor. But the thing captured may be purchased from the captor by a person belonging to a neutral state, or it may be recaptured. It becomes therefore necessary, as between the original owner and such purchaser, or between the original owner and the recaptor, to lay down some rule for determining at what time and under what circumstances the thing captured becomes prize, so that the property in it passes to the captor for all purposes. The law of nations upon this point was very vague and unsettled. It used to be said that property was not devested by capture until after possession had been retained twenty-four hours, or until the prize had been taken infra praesidia; or again, until the spes recuperandi was gone. The present rule is thus expressed by Lord Stowell:—"By the general practice of the law of nations a sentence of condemnation is at present deemed generally necessary, and a neutral purchaser in Europe during war looks to the legal sentence of condemnation as one of the title deeds of a ship, if he buys a prize vessel." Sentence of condemnation, that is, sentence that the thing captured is prize, and that consequently the property of the original owner in it is entirely devested, must be pronounced by a court of the capturing power duly constituted according to the law of nations. The prize court of the captor may sit in the territory of an ally, but not in that of a neutral. Questions of prize are by the English law disposed of in the courts of Admiralty. [ADMIRALTY.] (45 Geo. III. c. 72.)

PRIZE-MONEY. All the acts relating to army prize-money have been repealed by the 2 & 3 Will. IV. c. 53, which also enacts that all captures made by the army shall be divided according to such general rule of distribution as the king shall direct.

PROBABILITY, PROBABILITIES, THEORY OF. A conclusion is said to be known in two distinct ways; first, when it is derived from those principles (as we call them) which may be considered as common to all mankind, or which at least no one is found to deny; secondly, when it results, by a sure process of inference, from premises which are believed to be known. Whether these premises be properly known, that is to say, whether another person assuming to decide on the propriety or impropriety will be satisfied or not, is not a part of the present inquiry. That knowledge of the first kind exists is unquestioned, and most of the results of such knowledge are agreed upon. That knowledge of the second kind exists is also unquestioned, though two men may differ as to whether a given conclusion be part of it or not. The distinction, as elsewhere noticed [MATHEMATICS], is positive, easily apprehended, and useful; it exists moreover, and must exist, whatever may be the system of psychology on which one man or another may explain it.

In the exact sciences, demonstration is always effected in such a way as to show that nothing contradictory of the proposition demonstrated either is true or can have been true at any time. Two sides of a triangle are, were, and always will be, greater than the third; by which we mean that persons with minds constituted as ours are, must have admitted this, must now admit it, and must admit it in all time to come. Those who should deny the proposition must really hold that a whole may be less than its contained part: such is the alternative which geometrical demonstration offers for acceptance, and we should cease to consider a mind as the proper object of instruction which should prefer the alternative to the proposition. Such truths as these are not the subject of the present article.

The other class of conclusions consists of those which may be false, or which may have been false at one time, or may become so, without the necessity of our supposing an absolute and inconceivable difference of mental constitution between ourselves and the person who may have seen this falsehood, may now see it, or is to see it. Many such conclusions appear to be as certain as if they were absolutely demonstrated, until a close and (to those who have not considered the subject) a captious test is applied, which shows that this certainty is not what is called mathematical certainty. One of the most certain perhaps of all is this: a ball of iron suspended by a thread will fall to the ground when the thread is cut; every one is as well persuaded of this truth as of the two sides of a triangle being together greater than the third; those who have not studied geometry know the former much better than the latter. But let any one assert that he has seen, in a part of Africa unexplored except by himself, a ball of iron suspended in the air, which, though iron to the sight and touch and iron to every *chemical* experiment, not only remains in the air without support, but, when forced to the ground, rises again of itself to the same height. We should laugh and disbelieve it, but we could not disprove it; in spite of our laughter and unbelief, no man can know such a thing to be false. Let a number of credible persons solemnly declare that they have seen the same phenomenon, and our unbelief would be shaken: finally, let it be a matter, as it is called, of common notoriety, and let a continual succession of good witnesses passing and repassing constantly confirm each other in the recital above mentioned, and our positive disbelief would be changed into as positive a belief. But let a new witness declare that the natives use bows and arrows of the common form, in which the straight string of the bow, meaning that part of it which joins the extremities of the bow, is four or five times as long as the curved bow itself; though our disbelief of this first witness would not be sensibly stronger than our disbelief of the first witness in the preceding case, yet it must be of this kind, that any succession of respectable witnesses, however numerous, could never add any force to the fact in a mind which can properly appreciate the grounds of the assertion that a straight line is the shortest distance between two points. A million of witnesses could do no more than one to establish the fact stated, in the mind of a person who knows what geometrical demonstration is; though it is just possible that another, who only learns the connection of the sides of a triangle from experiment, may be capable of being convinced of the second assertion by evidence, as well as of the first.

The *probability* of an asserted fact or conclusion means, in common language, the degree of belief which we think we ought to accord to it, and it depends in each mind upon the amount of evidence offered, the degree in which that evidence is understood, the fitness of that mind to receive and be acted on by evidence, and in particular by the evidence which is offered. Evidence insufficient, or ill understood, or offered to a mind which is unduly credulous or sceptical, whether to the particular sort of evidence in question or to evidence in general, may give a low degree of probability, or none at all, to what another mind considers as indisputable; or the contrary. In the common use of the word, a result is said to be probable only when the mind inclines more or less to believe it, and improbable in the contrary case. The mathematical use of the term is rather different; but, till further notice, we retain the common signification.

We are going to treat belief as a QUANTITY, not only to speak of its more and less, but to submit that more and less to measurement. The phrase is unusual, but when a halfpenny is in the air, we half believe that *head* will fall uppermost, and we half believe in *tail;* this is what we mean when we say the chances are even. But the reader must remember that in our present subject belief does not mean that result of self-will which a person puts forward as his *opinion.* Without any wilful falsehood, men can contrive very frequently to disguise the real state of their minds with respect to a proposition, and to substitute their wishes for their beliefs; not their prejudices, for real prejudice *is* belief, but their wishes. The conclusion of the mind is thrust into a corner; and when, after all, it is necessary to declare it, we hear—I had all the time a *lurking* belief, &c. That lurking belief was the rightful owner, but the sovereign will had put a usurper in his place. The verb to *believe* has only one future form; what we shall believe, and what you will believe, are legitimate matters of conjecture. But "I will believe" is a declaration which is no more in our own power than "thou shalt believe" is in our own right. It has cost England centuries of struggle to tear the second out of the grammar of statesmen and divines; but how much longer it will take to get as well rid of the first is beyond the theory of probabilities to guess.

We mean by evidence, in the present inquiry, not merely oral or written testimony, but everything which disposes the mind, however little, to adopt or reject, including even the effect of previous knowledge. The value of evidence, that is, the extent it should go towards inducing belief, is really the subject of inquiry in a branch of exact science known by the name of the *theory of probabilities.* But how can the value of evidence be made a subject of measurement? why can this be done in the case of an amount of credibility more than in that of an amount[*] of benevolence, courage, or talent? We should assuredly think any one must be in a curious delusion who should suppose himself to have ascertained, from the data given by Homer, that the warlike skill of Achilles was exactly 552 times that of Thersites, and that Shakspere had done the former a foul wrong, for that he had made it only 237 times and a fraction. But what is the difference, in the nature of the inquiry we seek to institute, between attempts to measure prowess and probability? On the mode of answering this question it depends whether we are to make our subject merely, as heretofore, a kind of artificial method of judging the chances of a game of hazard; or a rational and exact mode of doing, when data are sufficient, that which we daily attempt to do, as well as we can, with our inaccurate appreciations of the circumstances of common life; and a science to be used, as are others of a mathematical nature, for accustoming ourselves to estimate or guess with something like accuracy, by habitual acquaintance with cases in which absolute accuracy is attainable.

When we consider all the circumstances which affect belief or opinion, both those which are external and those which depend on the mind which is exposed to them, it may well bewilder the imagination of a person not accustomed to the idea, when he hears of an attempt to reckon credibility in numbers, and to deduce what are called exact conclusions from hypotheses as to the force of assertions. To remove from the threshold of the subject the incredulity which must exist, and ought to exist in the first instance, let us suppose the other branches of science presented to a student not in their simple beginnings, but by a description of their ultimate physical objects. To put this beginner in a state parallel to that of readers in general with respect to the subject of probabilities, he must be of mature age, with very little knowledge of number, none of any other branch of mathematics, and no conception of the construction or use of any physical instrument, nor of the object and procedure of any one experiment. He might then be addressed as follows:—"You are, without moving from this earth, to track the motions of all the heavenly bodies, to be able to ascertain where they were or will be at any moment of time past or future, to measure their sizes, to weigh their contents, and to find the species and amount of insensible forces which, by some unknown means, they exercise on one another. You are to detect the existence of a subtle fluid which can neither be seen, heard, nor felt, to measure vibrations of which there are millions in a minute, and to trace the course of effects which travel hundreds of thousands of miles in a second. You are to weigh against each other atoms of matter of which it cannot be shown that millions put together would be visible to the eye." The person so addressed would not be less bewildered nor more disposed to treat the proposed results as fictions, than he who hears for the first time of a numerical theory of probabilities. But let us now reverse the method, and suppose the learner allowed to begin at the beginning. He first finds that, step by step, his rude notions of number are organised into a method of computation which enables him easily to perform more than he could have imagined the most subtle brain to have devised. From notions of the simplest kind connected with space, properties of figure become almost intuitive, of which he could at one time not have comprehended the description, far less the demonstration. By reasoning on the simplest properties of matter, such as can be proved to his senses, he finds no difficulty in tracing remote and complicated combinations of effects from the plainest causes, by which he learns to invert this process, and to reduce observed combinations to their simplest elements. But if, during this long and very gradual process, he were to keep continually before his mind those great results the knowledge of which he had been promised, looking to arrive at the fulfilment of the promise by some sudden acquisition of power, his whole course would be one of disappointment. He would be peeping forward a few pages in his Euclid, in the hope of seeing himself almost arrived at the means of calculating an eclipse or explaining the theory of colours, and would find that he was to learn how to make a square equal to a given figure instead.

Now the application of the preceding description to our present subject is as follows:—The beginner in exact science has usually no definite notions as to the end which he is to arrive at; nor do the terms algebra, geometry, mechanics, &c., suggest any associations beyond a vague notion that they are parts of a learned system. But it is impossible that the beginner in the subject of this article should be without an explicit and probably an exaggerated notion of what he is to attain. There is no unknown Greek or Arabic term the meaning of which must be slowly learned by the study of the science of which it is the name; the word *probability*, so well known in the common affairs of life, stares him in the face at the head of every page, and reminds him to be dissatisfied with the extent of power gained, up to the point at which he has arrived. Unless then he can make up his mind to descend, as a student would do who, having in his head the theory of gravitation and the laws of light, should lay by these grand ideas, and set himself to trace the consequences of the simple notion that two straight lines cannot enclose a space—he must be warned that he will be likely to quit the subject in disgust. We now proceed to the fundamental points of the theory.

That opinion may be formed with more or less strength, particularly when the subject-matters are of different species, is well known to every one from his own experience. The most decided republican in England, for instance, is not so sure of the wisdom of the Long Parliament as he is that all its members are now dead; and no royalist, however well persuaded of his tenets, thinks the Restoration was of as much consequence to this country as sun, wind, and rain. It matters nothing that the different degrees of assurance refer to very different matters, and are obtained in very different ways; that they are separate amounts of the same kind of feeling is universally felt and admitted. To make something like a gauge for these degrees of belief is not difficult; to apply it is a harder task, seeing that the cases which present circumstances of sufficiently definite character are seldom met with.

Suppose a box to contain 3 white and 4 black balls; it is easily admitted that it is more likely that a black ball should be drawn than a white one, on the supposition that the drawer does not see the balls. Or rather we should say it is easily admitted that every well regulated mind *ought* to think a black ball more likely than a white one: and that if any one should imagine the contrary, he has formed an opinion from prejudice, fancy, or want of proper consideration. Just as we should say that if all the balls were black, a black ball would certainly be drawn, so when a majority of the balls is black, and each one ball is as likely to be drawn as any other, there are more ways of drawing black than white, and we look upon the former as more obtainable, and more likely to be obtained, than the latter. Common experience makes us consider the black as more likely than white, when the number of black balls is much greater than that of white balls; as, if there were only 3 white balls, and a million of black ones. Here, as in other questions of magnitude, we can see a difference when the difference is great, which we must perhaps learn to see when it is small: it is plain enough that the black is more likely than the white when there are a million of black balls to one white; but not so easily grasped that the black is more likely than the white when there are five hundred thousand and one black balls to five hundred thousand white.

The next step to be made is the assertion that when there are 3 white and 4 black balls, the probability of drawing white is to that of drawing black in the proportion of 3 to 4; that is, if we could by a voluntary act make our impressions about the probability of future events of that strength which our reason tells us they ought to have, we should choose to expect a black ball more strongly than a white one in the proportion of 4 to 3. The principle on which we do this is the main point of the theory, the only objectionable part, if there be one: for all the rest is mathematical deduction.

The principle is as follows:—When any number of events, A, B, C, &c., are such that one and only one can happen at a time, and when a, b, c, &c., are the numbers of ways in which they can severally happen, the probabilities of the several events are in the proportions of the numbers a, b, c, &c. Returning to the preceding simple instance, we have an obvious negative reason for supposing that the probabilities should be as 4 to 3, since there is no imaginable ground for assuming, while the excess of black balls is the sole cause of the superior probability of drawing one of them, that this excess of probability should be in any other proportion than that of the excess of black balls. If we grant the following, namely, that the probability of having one or other out of two of the different results which a trial may give, is, or ought to be, the *sum*[*] of the probabilities of the two separately, we shall be obliged to admit positive reason for the preceding principle, as follows:—Suppose a box to contain 10 balls, marked 1, 2, &c. up to 10, and no others. A ball is to be drawn, and the drawer has in his mind an amount of hope, fear, or simple admission of possibility, as the case may be, as to the happening of each number. If the drawing of No. 1 be to gain him a prize, there is a certain amount of hope; if it be to procure him a loss, of fear; if neither one nor the other, of feeling that No. 1 may be that which is drawn. Now let either 1 or 2 bring the gain or loss; is the feeling of hope or fear doubled in strength? or rather, *ought* it to be doubled? He who admits this, admits the whole theory of probabilities, for all the rest is mathematical deduction. Let x be the proper numerical measure of the probability of drawing 1, or of drawing 2, &c.; these probabilities being equal, since there is, by the hypothesis, nothing to render one more likely than the other. Then, if the preceding be admitted, $2x$ is the probability that either 1 or 2 is drawn; $3x$, that either 1, 2, or 3 is drawn; and so on up to $10x$, which is the probability that one or other of the set 1, 2, 3, ... 10, shall be drawn. But since that a drawing shall take place is an absolute condition, one of the ten numbers must be drawn; hence x must be so taken that $10x$ shall be the numerical measure of certainty. It is indifferent what number is taken to stand for the exponent of certainty, so far as principles are concerned; but in a mathematical point of view, unity is more convenient than anything else. Let unity be adopted, then $10x=1$, or $x=\frac{1}{10}$. Hence the chance of drawing, say one of the three, 1, 2, 3, is $\frac{3}{10}$; and that of drawing one of the remaining 7 is $\frac{7}{10}$. If then the first three should be white balls, and the last seven black, the chance of a white ball is $\frac{3}{10}$, that of a black one is $\frac{7}{10}$; and a black ball is more likely than a white one in the proportion of 7 to 3, which being inequality in the proportion of 2⅓ to 1, the *odds* are said to be 2⅓ to one in favour of a black ball, or against a white one. By this we do not mean that every man *does*, in such a case, look for a black ball with an expectation 2⅓ times as great as his expectation of a white ball, but that, if he *could* measure the strength of his own feelings and adjust them with mathematical precision, he *would* proportion the strength of the two expectations in the preceding manner. And if money were to be spent upon the expectations, he may as reasonably give 2⅓*l*. for a black ball, before it appears, as 1*l*. for a white one. We do not naturally reckon probabilities by numbers; but nevertheless, we have some kind of estimating apparatus in our brains: Kant called it *a weighing machine with unstamped weights.*

---

[*] It is rather for the argument that we endeavour, however imperfectly, to make numerical standards of use in estimating every one of these qualities, which we put down at hazard before the matter of this note suggested itself. We are apt to compare the benevolence of two persons by the pecuniary results of their liberality; confounding the two qualities, but perhaps the very confusion arises partly from the numerical measure which is thereby supposed attainable. We form a vague notion of the comparative courage of two soldiers, by comparing the different amounts of danger which we think they have faced; a most unfair and fallacious test, but still indicative of the tendency to measure. Finally, we compare talent in what, speaking of the way it is now done, we can hardly call a more rational manner, by trials of what competitors can do under the same circumstances and in the same time.

[*] Disjunctive mention is a logical aggregation, a summation, of classes. When we say "He is either fool or mad," we say he belongs to the genus which contains the species *fool* and *mad*. To describe him in a word, we want a name for fool + mad. We never say "it is either man or brute;" we say "it is *animal*."

It thus appears that the theory of probabilities is simply the reduction to a numerical estimation, in cases which are perfectly known as to the number of events which may happen, of our comparative right to expect one or another event in preference to the rest. In the events of common life, we make estimations of this comparative right, but not *numerically*, because we are not in sufficient possession of the events which might have happened instead of the one which does happen. In such terms as barely possible, very unlikely, improbable, not improbable, as likely as not, rather likely, highly probable, almost certain, &c., we see a gradation which amounts to a rough attempt to make those comparisons which might be made numerically if the proper data could be obtained. The truth is, that every one naturally admits and practises the fundamental principles of this theory, though often, it may be, unskilfully. But it is not to be imagined that persons in general make an investigation like the preceding, nor indeed any investigation at all: how is it then that not only are these principles acquired, however imperfectly, by the majority of mankind, but the mathematical results which are obtained by those who professedly study the subject, are received almost universally; not only are they felt to be agreeable to common sense in a great majority of cases, but they are soon admitted to be sufficient indications that common sense is wrong, in the few cases in which they at first appear repugnant to it? The answer to this question leads to another view of the subject.

We all find, by every-day observation, that whenever an event of one kind happens permanently more often than one of another kind, there exists some reason for such frequency of occurrence, which, had it been inquired into before any event happened, would have enabled us to predict the frequency in question. So much is this the case, that if we were to take an observer to an urn in which were black and white balls, but how many of each he is not told, and were to make 1000 drawings, replacing the ball drawn after each drawing, and shaking the urn before every trial; if of the thousand drawings 822 were white and 178 black, he would be irresistibly led to conclude that there must be more white balls than black ones in the urn. Not that this is absolutely necessary; for it is barely possible that there may be only one white ball and 999 black ones, and that by a remarkable coincidence the sole white ball may have come up 822 times out of the 1000 trials. More than this, a person used to observation would conclude, not only that there are more white balls in the urn, but that the proportion of white and black balls does not differ very greatly from that of 822 to 178. There is a disposition, derived from experience, to think that events happen in the long run in some sort of manner connected with the facilities afforded for their happening beforehand: and hence follows a disposition to judge what those facilities were from observed events, as well as to predict events from observation of those facilities; and it may happen that one person would draw his notion of likelihood from the first, and another from the second. Thus, if we were to put the question, "What do you mean by saying that it is 5 to 3 for A against B?" one person might reply, "I mean that in the long run A will happen 5 times for every 3 times which B happens;" while another might say, "I mean that precedent circumstances are so arranged that for every three contingencies under which B may happen, there are 5 under which A may happen." If these two persons were to dispute which was the *true* mode of viewing the subject, they would be fighting about nothing; for both are true, and each of them follows from the other: but if they were to differ as to which is the *common* mode, we should feel rather disposed to side with the one who was for the first answer.

The following problems, illustrative of the connection between the two modes, are the results of mathematical investigation. The table used is that given in MEAN: but two decimal places must be made in column A, and four in column B; thus 451 opposite to 4 must be read as ·0451 opposite to ·04, similarly ·8931 comes opposite to 1·14, and ·9825 opposite to 1·68.

PROBLEM 1.—The probabilities of P and Q, at any one trial, are as a to b, that is, it is a to b for P against Q, and b to a for Q against P. A large number of trials $n(a+b)$ is made; what are the chances that the number of Ps which happen shall lie between $n\,a+l$ and $n\,a-l$, and (of course) the number of Qs between $n\,b-l$ and $n\,b+l$ (l being small compared with $n\,a$ or $n\,b$)?

RULE.—Calculate $(2\,l+1)\div\sqrt{\left(\frac{8\,n\,a\,b}{a+b}\right)}$; let this be the A of the table (altered as above); then the corresponding B, altered as above, is the probability required.

EXAMPLE.—It is 2 to 1 that a throw with a die shall give 3, 4, 5, or 6, and not 1 or 2; what is the chance that, in 12,000 throws, the number which gives 3, 4, 5, or 6 shall lie between 8000 + 100 and 8000 − 100. Here $a=2$, $b=1$, $n=4000$, $l=100$, and the complete calculation by logarithms* (which we insert merely as a guide to the readiest mode of treating more complicated cases) is as follows:—

$$\begin{array}{lrrr}
n=4000 & 3{\cdot}6021 & 2\,l+1=201 & 2{\cdot}3032 \\
a=\quad 2 & {\cdot}3010 & & 2{\cdot}1646 \\
b=\quad 1 & {\cdot}0000 & & \\ \cline{4-4}
\quad\quad\ 8 & {\cdot}9031 & 1{\cdot}376 & {\cdot}1386 \\ \cline{2-2}
 & 4{\cdot}8062 & & \\
a+b=3 & {\cdot}4771 & & \\ \cline{2-2}
 & 2)4{\cdot}3291 & & \\ \cline{2-2}
 & 2{\cdot}1646 & &
\end{array}$$

In the table, A being 1·38, B is ·9490, which is more than near enough for the purpose, say ·95: the result then is that ·95 is the chance in favour of the throws which give 3, 4, 5, or 6 out of 12,000 throws lying between 8000 + 100 and 8000 − 100, whence ·05 is the chance against it; that is, it is about 95 to 5, or 19 to 1, that the throws shall so lie. A few instances of this kind will show how completely, in the long run, events may be expected to happen in numbers nearly proportional to what are called, when the precedent circumstances are fully known, their probabilities of happening.

PROBLEM 2.—In the preceding problem, to find l so that there may be a given probability that the Ps shall lie between $n\,a+l$ and $n\,a-l$.

RULE.—Reduce the fraction which represents the given probability to a decimal fraction, and take the A corresponding to the B which is nearest to this fraction in the table; multiply by the square root above described, subtract 1, and divide by 2; the whole number nearest to the result is the answer required for l.

EXAMPLE.—In the preceding example, find l so that it is an even chance that the number of throws out of 12,000 which give 3, 4, 5, or 6 shall lie between $8000-l$ and $8000+l$. Here ½ or ·5 is the given probability, the nearest to it in column B is ·5027 to which A is ·48, which multiplied by the square root (or the number whose logarithm is 2·1646) is 66·9: subtract 1 and divide by 2, which gives 33 very nearly: hence it is an even chance (very nearly) that the number of throws out of 12,000, which give 3, 4, 5, or 6 lie between 8000 − 33 and 8000 + 33.

PROBLEM 3.—In $a+b$ trials, a and b not being small numbers, and nothing whatever being known except what these trials tell, it is found that P happens a times, and Q happens b times; from which it is exceedingly likely that the probabilities of P and Q happening at a single trial would have been nearly as a to b, if we had known enough to form an *à priori* opinion. This we cannot do, by hypothesis: but, judging from the preceding events, with what degree of probability may we infer that if we had been able to form an *à priori* opinion, the odds for P against Q would have appeared to us to lie between $a-k$ to $b+k$ and $a+k$ to $b-k$?

RULE.—Calculate $k\div\sqrt{\left(\frac{2\,a\,b}{a+b}\right)}$; let this be A (in the table): then the corresponding B is the probability required.

EXAMPLE.—In 600 drawings from an urn, the ball being replaced after each drawing, there were 418 white balls and 182 black ones. What is the probability that the proportion of white and black balls in the urn lies between that of $418-10$ to $182+10$ and $418+10$ to $182-10$, or that of 1000 to 471 and 1000 to 402? Here $a=418$, $b=182$. $k=10$; the square root above mentioned has 1·2021 for its logarithm, and 10 divided by this square root gives ·63 nearly. And A being ·63, B is also ·63 very nearly, which is the probability required; or it is 63 to 37, or nearly 2 to 1, that for every 1000 white balls in the urn, there are between 402 and 471 black ones.

---

* In this, and many other cases, the four-figure logarithms, published by Taylor and Walton on a card, will be found by far the most convenient.

PROBLEM 4.—When P happens much oftener than Q, we feel a very high degree of probability (moral certainty) that the same thing would happen in the long run, or would continue how long soever we might go on trying, unless there should arrive some change of circumstances. But when P does not happen much oftener than Q, we do not feel the same degree of assurance; for though Q might really happen oftener than P in the long run, yet the casual fluctuations of events might make the contrary appear in any one set of trials. Suppose then that in $a+b$ trials, P has happened a times, and Q has happened b times, a and b being nearly equal: what presumption can thence be derived that the excess will be on the same side in the long run on which it is in the $a+b$ trials?

RULE.—Divide the difference of a and b by the square root of twice their sum: let the result be A, and find the corresponding B; to this add 1, and divide by 2: the result is the probability required.

EXAMPLE.—Buffon, in a particular experiment, had to throw a coin (say a halfpenny) 4140 times; the result was 2048 heads and 2092 tails: what is the probability that some excess of tail over head would have continued for ever; that is, that the coin he used had in its construction some mechanical tendency to fall tail rather than head? Here $a=2048$, $b=2092$; the difference divided by the square root of twice the sum is ·48, which being A, B is ·50, and 1·50 divided by 2 is ·75, the probability required. This is $\frac{3}{4}$, so that it is 3 to 1 that some excess or other of tails would be found in the long run. Observe however that this does not mean an excess to the amount of 44 in every 4140 trials; but only *some* excess, small or great: observe also that the character of the mint and its processes are supposed wholly unknown, so that no conclusion can be formed about the character of the coin except from the observed event.

The experiment of Buffon, and its particular object, will be found in the 'Essay on Probabilities and Life Contingencies,' in the 'Cabinet Cyclopædia;' in which work will also be found a larger collection of such problems as the preceding, with fuller explanation and more extensive tables. These problems have been here introduced that the reader may have an opportunity of comparing and verifying the general sameness of results which follows from the two (perhaps) apparently differing notions from which the idea of the measure of probability may be derived.

Previously to laying down a few general rules, we shall notice the error to which persons who have not thought on the subject are most liable: this is a confusion between the sort of confidence which is to be given to a result of the theory of probabilities, and that which is claimed by actual demonstration. Many persons are not aware that out of mathematics the greater number of conclusions are *probable* results: many of them, it is true, so highly probable that their chance of falsehood does not amount to that of drawing a black ball from among a million of white ones; but still not absolutely demonstrated. These highly probable results (so probable that the word probable in its common sense is weak as applied to them) form the ordinary knowledge of common life, and being practical certainties, are considered and mentioned as certainties, the imperceptibly small chance that they may not be true being disregarded. Hence it happens that when a result of this theory is announced, with its proper chance annexed, and though the probability of its truth is so high that it may rank with the moral certainties of ordinary life, there is a morbid disposition to dwell rather upon the one way in which the proposition may fail, than upon the million of equally possible ways in which it may be true. Thus if it be said that it is ten millions to one that P will happen, and not Q, therefore it is morally certain that P will happen—it is objected, But how do we know that the very next event will not be precisely the one of ten millions which is Q and not P? The answer is, we do not *know* it in the absolute sense of the word; if we thus knew it, it would be a certainty that P would happen, and whether P would happen or not would not be a question for the theory of probabilities at all: but we do know it in the common sense of the word, since there are hundreds of conclusions which all men call knowledge, which are not so probable that they can be reasonably shown to have ten millions to one in their favour.

Another way in which the confusion we have mentioned shows itself is, in the habit of reasoning against the probable truths just alluded to, by arguments which could only be valid against an assertion that these truths were absolutely demonstrated. In compliance with the forms of language, those who advance such truths treat them as (moral) certainties: the opponent overthrows their (mathematical) certainty, and the fallacy lies in his supposing that he has thereby shown them not to possess that sort of truth which was claimed for them. For example, a medical man gives his opinion that a crime committed without any apparent motive is an indication of insanity: a newspaper ridicules this opinion, and asks, Are there no motives then which cannot be discovered? Now, if by *apparent* was meant apparent on the surface, or with slight examination, and if by *indication* was meant an absolute indication, certainly inexplicable except by the supposition of insanity, the answer is complete, and the opinion shown to be untenable. But suppose the energies of many acute persons and the resources of a whole nation to fail in making the motive of a crime apparent, and that this is what is meant by there being no apparent motive; suppose moreover that by an indication of insanity is meant a circumstance which renders insanity so moderately probable that the hypothesis deserves to be weighed: the answer then is wholly irrelevant. The opinion, expanded into an argument, is—a crime committed absolutely without motive or object shows insanity; a motive, if it exist, may almost certainly be discovered by proper exertions; consequently the appearance of no motive, after all exertions to discover one have been tried, makes it most likely * that the crime was an act of insanity; it is in fact as likely that the crime was an act of insanity, as it was unlikely that the exertions to discover a motive should have failed, if there had been a motive.

The application of this theory to pure logic is contained in the consideration of testimony, argument, and their combination. The following rules † will be found demonstrated in De Morgan's 'Formal Logic,' ch. x.

Testimony, or authority—which means only testimony of great force, as the word is commonly used—speaks to the truth or falsehood of the assertion. But argument speaks, not to the truth or falsehood of the conclusion, but to the validity of the mode of establishing it. An argument may be invalid, either by false premises or bad logic: and yet the conclusion may be true. Consequently, the probability of an argument being valid is a totally different thing from that of the conclusion being true.

The effect of testimony, as also of argument, must depend upon the initial state of the receiver's mind with reference to the conclusion asserted. But though the receiver himself may stand in a very different position from the witnesses who bring him testimony, yet in the mathematical formulæ he ranks but as one of those witnesses: if his initial state be that it is 999 to 1 against the conclusion, the results of the theory are the same as if he, being unbiassed, found an additional witness to deny the assertion for whose correctness it is in his mind, *à priori*, 999 to 1. A person without any bias on his mind begins with an even chance for the assertion. And a witness of credibility μ, who asserts, ranks as a witness of credibility $1-\mu$, who denies. The following rules are given in mathematical form, for consistency with the rest of the article: the non-mathematical reader will find them reduced to arithmetical rules in De Morgan's 'Syllabus of a Proposed System of Logic,' 1860.

Let a number of witnesses, of credibilities μ, μ', &c., affirm: let others, of credibilities $\nu, \nu', \ldots$, deny. By the credibility of a witness we mean the belief we have of an assertion of his being correct, before we turn our attention to the particular character of that assertion. Then the odds in favour of the assertion are $\mu\times\mu'\times\ldots\times(1-\nu)\times(1-\nu')\ldots$ to $(1-\mu)\times(1-\mu')\times\ldots\times\nu\times\nu'\ldots$ Let the probability of the assertion thence obtained (the first of the two divided by their sum) be called M: and remember that the receiver himself is one of those witnesses, as before explained.

Let a number of arguments of which the several probabilities of validity (that is, of their proving their conclusions true) be $a, a', \ldots$. The probability that the conclusion is proved—that is, that one or more are valid—is $1-(1-a)(1-a')\ldots$ If arguments be produced for the contradictory conclusion, of validities b, b', &c., then $1-(1-b)(1-b')\ldots$ is the probability that the conclusion is disproved. We speak of separate cases: the combination of arguments for and against will be instantly seen. Let these results be A and B. We may treat the conclusion, as now asserted to an unbiassed mind by a single witness of credibility M, supported by one argument of validity A, and opposed by one argument of validity B. The only difference is that if there be a plurality of witnesses or of arguments, we have to calculate M, A, B; which, when there is one only of each kind, are supposed given.

When testimony and argument are combined, the odds in favour of the conclusion are $M(1-B)$ to $(1-M)(1-A)$. The following cases may be distinguished:—

1. No evidence; arguments on both sides. Here $M=\frac{1}{2}$, and the *odds* ‡ are $1-B$ to $1-A$. When A and B are very near to unity, or

---

* When this paragraph was written, there was a run against the hypothesis of insanity in criminal cases: since that time there has been a longer and stronger run in favour of it. Had this article been now first written, in all probability the illustration would have been drawn from the excess opposite to that chosen for comment in the text.

† The account of this matter given in the 'Penny Cyclopædia' is not correct, though something nearer the mark than anything which preceded. The logicians had constantly confounded the probability of validity of an argument with the probability of truth of its conclusion; and the article just referred to followed them in their principle, though not in their details.

‡ This word is connected with gambling associations; and so is the word *chance*. We substitute *probability* for the second word, which is used ambiguously [CHANCE]: but we cannot conveniently dispense with *odds*; the following anecdote, however, may go some way to purify the polluted word. It is told by the distinguished experimenter, Professor Faraday, in a lecture 'On Mental Training' (12mo, 1854). "When I was young, I received from one well able to aid a learner in his endeavours towards self-improvement, a curious lesson in the mode of estimating the amount of belief one might be induced to

both arguments very powerful, it is to be assumed that the mind does not see the ratio of the small quantities, and the question is evenly balanced.

2. No evidence; only argument for. The odds are 1 to 1—A; taken by all the logicians who have considered the subject to be A to 1—A. The first result is always greater than the second; which means that even if the argument be invalid, the conclusion may still be true, and has some probability left.

3. A witness of given credibility does not add so much to the force of the conclusion as an argument of the same probability of validity. We introduce this assertion as one of common sense: if the witness be wrong the assertion is false: if the argument be invalid, the assertion may still be true; consequently the argument is better than the witness. How do the formulæ verify this? As follows:—if a be the probability of both, the odds for the truth are altered by the witness in the proportion of a to $1-a$ and by the argument in the greater proportion of 1 to $1-a$.

4. Any argument, however slight its force, adds something to the force of its conclusion: for alteration in the ratio of 1 to $1-a$ is increase, let a be ever so small. But it must be remembered that this is only true of the argument *per se*, and has no reference to the possibility of the weakness of the argument being itself an argument on the other side. If a weak argument be brought forward by a person who most probably would know the stronger ones, if there were any, the argument on the other side just spoken of may arise. On this, however, and other points, our space obliges us to content ourselves with the reference already made.

The various problems of which the solutions have been given are mathematical consequences of the definition of probability. Every such problem is simply one of combinations, however much the length of detail, and the number of mathematical abbreviations of the process of combining, may tend to make us lose sight of the first principle. At the same time it is found requisite to establish a few simple fundamental propositions, which we shall cite, with some consequences. As we are not writing an elementary treatise, we shall not demonstrate these propositions, referring the student to any of the modern works hereinafter cited. The probabilities of the events A, B, C, &c., are denoted by a, b, c, &c.

1. By a, the probability of A, is meant the fraction which the number of cases favourable to the happening of A is of the whole number of cases, that is, both of those in which A can happen, and those in which it cannot: all cases being equally likely. And the probability that A will not happen is $1-a$.

2. When A and B are events independent of each other, so that the happening of either in no way promotes nor retards the happening of the other, the probability that both shall happen is ab; that neither shall happen, $1-a-b+ab$; that one only shall happen, $a+b-2ab$; that one or both shall happen, $a+b-ab$.

3. When A and B are mutually exclusive, that is, when if one happen the other cannot, the probability that one or other shall happen is $a+b$; and that neither shall happen, $1-a-b$.

4. If either A or B must happen, $a+b=1$; and if n trials are to be made, the several terms in the expansion of $(a+b)^n$ are the chances of the arrivals denoted by their exponents. Thus—

a^n is the chance that all are As.

$na^{n-1}b$, that $n-1$ are As and one is B.

$n\dfrac{n-1}{2}a^{n-2}b$, that $n-2$ are As and two are Bs, &c.

5. When an event has happened which may have sprung from any one of the sets of circumstances which we may describe by A, B, C, D, &c., and it is desired to find what is the probability of the event which did happen having arisen from one or another set, proceed as follows:—Had the circumstances denoted by A certainly existed, and the event been a contingency, let a be the probability that those circumstances would have produced the event; or briefly, let a be the probability that A, when certain, brings about the event. Let b be the same for B certain, c for C, &c. Then the probability that it was A which brought about the event which did happen, is the first of the following set:—

$$\frac{a}{a+b+c+\&c.},\qquad \frac{b}{a+b+c+\&c.},\qquad \frac{c}{a+b+c+\&c.},\ \&c.$$

the probability that it was B is the second, that it was C the third, and so on. Or, when convenient, instead of a, b, c, &c., may be substituted any whole numbers which are proportional to them. For example, let there be three lotteries, containing balls as follows:—

all white,	4 white, 1 black,	2 white, 7 black.

A drawing has been made three times from one of these, but from which is not known, the ball being replaced after the drawing, and every drawing has given a white ball. Required the chances in favour of each of these lotteries having been the one drawn from. If it had been the first, the chance of the event would have been 1 (or certainty); if it had been the second, the chance of the event would have been $\frac{4}{5}\times\frac{4}{5}\times\frac{4}{5}$, or, $\frac{64}{125}$; if it had been the third, the chance would have been $\frac{2}{9}\times\frac{2}{9}\times\frac{2}{9}$, or, $\frac{8}{729}$. The numerators of these fractions, reduced to a common denominator, are 91125, 46656, and 1000; whence the probability that the lottery drawn from was the first, is

$$\frac{91125}{91125+46656+1000}, \text{ or } \frac{91125}{138781};$$

and the probabilities of the second and third lotteries are

$$\frac{46656}{138781} \text{ and } \frac{1000}{138781}.$$

The preceding question is well calculated to show the meaning of questions in this theory, which is thus seen to be applied to events, not because they are *uncertain*, but because they are *unknown*. So soon as the lottery is chosen, it is certain which it is, but since it is not known to the drawer, it is to him as much a contingency as it was before it was chosen.

6. When, in such a case as the preceding, it is required to know the probabilities of the events which may happen at any further trials, the probability of each lottery having been the one in question is to be multiplied by the probability of the new event arising from that lottery taken as certain, and the results added together. Thus, suppose there are two lotteries, one having all white balls, and the other equal numbers of white and black balls; two drawings have been made from one of them (not known) and both drawings have given a white ball; what is the probability that a third drawing from the same lottery would also give a white ball? The chances for the two lotteries are found by the last to be $\frac{4}{5}$ and $\frac{1}{5}$, while the chances of a white ball from one and the other are 1 and $\frac{1}{2}$. It follows that $\frac{4}{5}\times 1+\frac{1}{5}\times\frac{1}{2}$, or $\frac{9}{10}$, is the chance of the third drawing giving a white ball.

7. If A or B must happen at every trial, and if in m trials nothing but A has happened, and if we know nothing whatever about the nature of preceding circumstances, then it is $m+1$ to 1 that A shall happen at the next trial, and $m+1$ to k that A shall happen throughout the next k trials. But if in $m+n$ trials A have occurred m times and B n times, it is $m+1$ to $n+1$ that A shall occur at the next trial.

8. Every event that *can* happen *must* happen, if trials enough be made; and not only must happen, but must happen any number of times in succession. For example, if there be only one white ball to 100 black ones in an urn, and if drawings enough be made, the ball drawn being always returned and the urn properly shaken before a new trial, a person who goes on must at last draw that single white ball 1000 times running. This is a conclusion which the beginner cannot receive, particularly when he is told that 1,000,000 might be written for 1000, or any other number however high. Nevertheless, it will, in the course of his studies, not only be made clear to him, but it will also be shown that it is a conclusion which may be made obvious to common sense without any very profound mathematics.

9. If the odds against an event happening at any one trial be n to 1, there is an even chance of its happening in $\cdot 69\times n$ trials,* it is 10 to 1 that it happens in $2\cdot 40\times n$ trials, 100 to 1 that it happens in $4\cdot 62\times n$ trials, 1000 to 1 that it happens in $6\cdot 91\times n$ trials, and 10,000 to 1 that it happens in $9\cdot 21\times n$ trials. Thus if it be 200 to 1 against success in any one trial, $9\cdot 21\times 200$ being 1842, it is 10,000 to 1 that there shall be one success at least in about 1842 trials. But if a person should make 1000 trials without one success, he would have no right to say that it is 10,000 to 1 in favour of one or more successes in the next 842 trials.

10. When any sum depends upon a contingent event, the present value of that sum is such a fraction of it as the probability of the event happening is of unity. Thus 20*l.* to be gained if an event happen against which it is 7 to 1, is now worth only the eighth part of 20*l.*

There are no questions in the whole range of applied mathematics which require such close attention, and in which it is so difficult to escape error, as those which occur in the theory of probabilities. This makes it hard to lay down in a short space either maxims or examples sufficient to be really of use in advancing the student's progress: and

---

attach to our conclusions. That person was Dr. Wollaston, who, upon a given point, was induced to offer me a wager of two to one on the affirmative. I rather impertinently quoted Butler's well-known lines—

> 'Quoth she, I've heard old cunning stagers
> Say fools for arguments use wagers,'

about the kind of persons who use wagers for argument, and he gently explained to me that he considered such a wager not as a thoughtless thing, but as the expression of the amount of belief in the mind of the person offering it; combining this curious application of the wager, as a *meter*, with the necessity that ever existed of drawing conclusions, not absolute, but proportionate to the evidence."

* The numbers ·69, 2·40, &c., are all approximations.

of all subjects, there is no one in which writers of every grade have so frequently or so strangely made mistakes of mere inadvertence. One was pointed out about twenty years ago ('Camb. Phil. Trans.') into which both Laplace and Poisson had fallen, one after the other; but the discoverer of their slip proved himself signally liable to greater ones a very little while after. ('Cab. Cyclop.: Probability and Life Insurance,' p. 28.)

We shall conclude by a brief account of the historical progress of this branch of science; referring the reader for more detail to Montucla, and to the Treatise 'On Probability,' in the 'Library of Useful Knowledge.' Those who cultivated games of chance must at all times have had a general notion of combinations which were more probable than others, and must have seen that those cases of which there were most to happen, always did in reality happen most often. They could not fail to know, by reckoning on their fingers, that out of, for instance, all the throws of a pair of dice, there are only six doublets, and thirty other equally possible cases; nor could they have missed knowing that this must be the reason why doublets occur seldom in comparison with other throws. Notwithstanding this, the mathematical history of the subject usually dates from a fragment by Galileo, which merely shows why 10 can be oftener thrown on three dice than 9, and two problems proposed by Chevalier de Méré to Pascal, in 1654, concerning certain points connected with games of chance.

That the history of *correct* investigation dates from this period there can be little doubt, but the subject had been previously considered by Cardan, in a work, 'De Ludo Aleæ,' published from his manuscript in the first volume of the collected edition of his works, and never separately; and also so badly printed as to be almost unintelligible; circumstances both of which have probably contributed to keep it, as it has been kept, totally out of view. Cardan's theory is perfectly false: he supposes, for example, that since there are six faces to a die, it will happen in the long run that each face will come up once in six throws, which is true when many collections of six throws are averaged; but from this he draws the false conclusion that it is an even chance that any one face comes up in three throws. His numerical reasoning is therefore totally incorrect; but his notions on the general subject of probability are reasonably sound. Fortune, according to him, does not decide the general average of the play, but only the deviations on one side and the other which a small number of cases present; and experiment would, he says, prove that the long run would agree with the predictions of theory; it were to be wished that he had tried it on his own theory. This treatise was written about 1564, and published in 1663. But before this, in 1657, the tract of Huyghens, 'De Ratiociniis in Ludo Aleæ,' was published as an appendix to Schooten's 'Exercitationes Geometricæ,' being not only the first regular treatise, but the first which applies the theory to chances of loss or gain. It was translated into English, with additions, in 1692, the reputed translator being Motte, the secretary of the Royal Society. Then followed the 'Analyse des Jeux de Hasard,' by Montmort (first edition 1708, second, enlarged, 1713), a work of higher mathematical pretensions. The 'Ars Conjectandi,' of James Bernoulli, posthumously published by his nephew Nicolas, in 1713 (and which, it may be worth noting, is not contained in the collection of James Bernoulli's works), gives the first glimpse of the more difficult class of problems in which processes containing very large numbers are abbreviated by mathematical analysis. This was carried still further by De Moivre, whose first work, a paper, 'De Mensura Sortis' ('Phil. Trans.,' 1711), was expanded into his celebrated treatise on the doctrine of chances, first edition 1718 (not 1716, as frequently stated), second edition 1738, third edition, with his 'Treatise on Life Annuities,' 1756. The next step was made by Bayes ('Phil. Trans.,' 1763 and 1764), who first considered the probability of hypotheses as deduced from observed events.

The great work of Laplace (first edition 1812, third 1820) had in great part appeared at various previous times in the 'Memoirs' of the Academy of Sciences. It is remarkable, first by the extension of methods which it furnishes; secondly, by its giving at one view the whole state of the science and its applications; thirdly, by the particular attention given to the application of the theory to the results of observation. [Mean; Least Squares.] The next step in the history is Poisson's 'Recherches sur les Probabilités des Jugemens,' 1837, which gives the grand results of Laplace by a somewhat different analysis, and applies them particularly to the decisions of courts of law. This species of application had been before considered by Condorcet, in his 'Essai sur l'Application de l'Analyse à la Probabilité des Decisions,' Paris, 1785. It may also be worth while to mention the 'Traité de Calcul Conjectural,' of Parisot, Paris, 1810, a work which deals largely in the theory of simple combinations. The elementary work of longest standing, which exhibits some view of the higher mathematical applications, is the 'Traité Elémentaire du Calcul des Probabilités,' by M. Lacroix (second edition, 1822). The 'Essai Philosophique' of Laplace, which is an introduction to the third edition of his theory, contains no mathematics, and may be usefully read with any elementary treatise. The 'Instructions Populaires sur le Calcul des Probabilités' by M. Quetelet, Brussels, 1828, contains the most elementary view of the subject, and uses only simple arithmetic.

In England, since the publication of Simpson's 'Laws of Chance,' 1740, and the 'Laws of Chance,' by Samuel Clark, 1758, little was written on the mathematical theory except so far as it had reference to life annuities and assurance, until a very recent period. About 1830 Messrs. Lubbock and Drinkwater (Bethune) published a tract 'On Probability,' in the 'Library of Useful Knowledge,' giving more general methods of applying modern algebraical investigation than had before appeared in this country: by a binder's mistake this work is often attributed to Mr. De Morgan. In 1837, the article 'Theory of Probabilities,' in the 'Encyclopædia Metropolitana,' written by Mr. De Morgan, gave the results and methods of Laplace on most of the great questions of the theory. The 'Essay on Probabilities, and on their Application to Life Contingencies and Insurance Offices,' published by the same writer in the 'Cabinet Cyclopædia,' 1838, exhibits the principles without mathematical investigation, and the results arranged in rules for use. The article on 'Probability' in the new edition of the 'Encyclopædia Metropolitana,' by Mr. Galloway, gives the mathematical investigation of the higher parts of the theory, following the methods of Poisson. This treatise is published separately.

On subjects connected with this article, see Gaming; Risk; Wager; Mean; Least Squares; Observation and Experiment; Weight of Observations; Annuity; Mortality; Reversion, &c.

PROBATE. [Will.]

PROBATE, COURT OF. The grant of letters of administration of the effects of persons dying intestate, and of probate of the wills of testators, which were formerly the prerogative of the Ecclesiastical Courts [Ecclesiastical Courts], have been recently (20 & 21 Vict. c. 77) vested in a newly established court, called the Court of Probate. The functions of this court are confined entirely to deciding upon the authenticity of wills, and upon the proper persons to whom administration is to be committed, when no will exists. With the distribution of the property of deceased persons, and the rights of the various parties who claim it beneficially, the court has nothing to do. These matters must be decided by the courts of law and equity, as before the passing of the Act. The duties of executors and administrators remain the same as formerly. A central registry of wills and administration is established in London, and district registrars are established in forty of the principal towns of England. The office or registry in which probate or a grant of administration is to be sought, is no longer to be determined by the locality of the *assets* of the deceased person, but by the place where the deceased had a fixed abode at the time of death. Should the testator or intestate have a permanent place of residence in one of the registry districts at the time of his decease, probate or grant of administration may be obtained there; but the executors or parties claiming administration may, if they think fit, apply to the principal or metropolitan registry, and this may in some cases be found more convenient. Original wills proved in the country will be preserved in the district registries; but copies of them will be transmitted to the principal registry in London, so that in future the metropolitan registry will be the most convenient office of search for any will whatsoever.

The practice of the Court of Probate has been thrown open to the whole legal profession, so that the close monopoly of testamentary business formerly enjoyed by advocates and proctors is at an end. The court is presided over by a single judge, who sits at Westminster. An appeal lies from his decision direct to the House of Lords.

In cases where a person dies in one of the forty districts, leaving personal property under 200*l.*, the judge of the County Court of the district has jurisdiction should any contention arise, but from his decision an appeal, which is final, lies to the Court of Probate.

One principal advantage of the new system lies in the removal of all difficulty as to the question where a will ought to be proved, and the old question of *bona notabilia*, on which the necessity of obtaining prerogative probate or administration was founded. The rules of evidence in the Court of Probate are to be the same as those in courts of law and equity, while its proceedings are likewise assimilated to those of the courts of common law.

The duties raised in the Probate Court yielded in the year ending March 31, 1860, the sum of 3,463,226*l.*, including the succession duties. The legacy duty is charged on legacies of the value of 20*l.* and upwards out of personal estate or charged upon real estate, and upon every share of residue. Legacy to a husband or wife is exempt from duty. To a child, the husband of a child, a parent, or any lineal descendant or ancestor of the deceased, the duty is 1*l.* per cent.; to a brother or sister or their descendants, 3*l.* per cent.; to an uncle or aunt or their descendants, 5*l.* per cent.; to a great uncle or great aunt or their descendants, 6*l.* per cent.; to any other relation or any stranger in blood, 10*l.* per cent. The probate duty is payable on the total sum left by the deceased. For sums above 20*l.* and not exceeding 100*l.* the duty is 10*s.* if there is a will; and if there is no will the duty of 10*s.* is chargeable on sums of 20*l.* and not exceeding 50*l.* The duties continue to increase according to a certain scale. The succession duties on real estate have the same scale, and the valuation is made according to the worth as an annuity.

PROBLEM (πρόβλημα) means simply a thing put forward or proposed. In mathematical language it is anything which is required to be done, and in the earlier writers is distinguished from a theorem, or assertion to be proved, in that the latter does not require any specific object to be effected. Thus, "all the angles of a triangle are together equal to two right angles" is to be shown or made evident, and is a theorem; but "to draw a circle through three given points" presents an object to be effected, and is a problem. But it must be remembered that this difference lies more in the nature of the result than in the method; for the solution of this problem, so called, is an intuitive corollary from the theorem that if three points be joined, and perpendiculars be drawn bisecting two of the joining lines, the intersection of these perpendiculars is equidistant from the three points. It is also to be noted that this distinction of theorem and problem appears neither in the Greek of Euclid, Apollonius, nor Archimedes, the general term employed by all three, and in all cases, being *πρότασις*, which is translated by proposition. The distinction then is of a later date, and is the work of annotators; it appears in Pappus, according to the Latin of Commandine. It does not appear in the translation of Euclid by Athelard (which goes by the name of Campanus); and the first edition of the Elements in which we find it is the subsequent edition of Zambertus. If we leave the modern followers of the old geometers, we find the word problem used in its simple etymological sense of something proposed; but for the most part employed when the something proposed contains, or has contained, a remarkable difficulty. Thus to this day we talk of the problem of three bodies, as being one of the methods which are hoped to be found capable of decided improvement. In algebra the word is variously used, though, according to the ancient distinction, the solution of any equation of condition should be called a problem, and the establishment of any identity a theorem.

PROCESS. This term, in its original sense, comprehends the whole of the proceedings which take place, and are recorded by the court, in the course of a suit, criminal or civil, previous to final judgment. In this sense the word (*processus, procès*) is used in the French and Scotch laws. In its more ordinary and limited signification, the term is applied to the writs which issue out of any court for the purpose of compelling the parties to a suit, and other persons whose co-operation is required, to do some act connected with the progress of the suit. In this sense, also, process is either civil or criminal

Civil process was formerly, and until lately, practically divided into original, mesne (intermediate), and final process.

Original process, more commonly known as original writs, issued out of the common-law side or department of the Court of Chancery. Since the substitution for it of *writs of summons*, the latter are sometimes, though erroneously, called original process.

Mesne process is that which issues between the first writ and final judgment, including writs issued for the purpose of compelling the attendance of jurors and of witnesses, and for other collateral purposes. To avoid the expense and delay of an original writ, it was usual to commence actions by mesne process, founded upon a supposed original writ which never had in fact issued; and, by degrees, all process before final judgment, except the original writ, acquired the name of mesne process, even in cases where it formed the legal as well as the actual commencement of the suit, as in *scire facias, auditâ querelâ*, &c.

Final process is the term applied to express writs of execution. [Execution.]

Mesne and final process are sometimes called judicial process, because they issue under the authority of the court in which the action is pending. A great variety existed in the different forms of process by which actions were formerly commenced in the three superior common-law courts; but in all actions the process is now a *writ of summons*, in a form prescribed by statute, which is addressed to the defendant, and requires him to cause an appearance to be entered within eight days from the service of the writ. If the writ be served on the defendant, or so served that it must have come to his knowledge, and he does not enter an appearance, the plaintiff may sign judgment by default.

Arrest upon *mesne* process (as it is called in the statute) was taken away by 1 & 2 Vict. c. 110, except in cases where an arrest is ordered by the court or a judge; in which case a *capias* may issue at the same time as the writ of summons.

(See 3 & 4 Will. IV. c. 27, s. 36; 2 & 3 Vict. c. 27, s. 3; the Common Law Procedure Acts of 1852, 1854, and 1860; the Bills of Exchange Act, 1855; and the Bankrupt Law Consolidation Act.)

Criminal Process.—Where an indictment [Indictment] for treason or felony is found by a grand jury, process of *capias* issues to the sheriff, commanding him to arrest the indictee. But where an indictment found, or an information filed, charges the party with a misdemeanor only, the process is at common law a *venire facias*, being a command to the sheriff to cause the indictee, &c., to come into court, which, under this process, must be done by summoning him. If the indictee, &c., do not obey the summons, and it appears by the return that the indictee, &c., has lands in the county, a writ of *distringas* issues, commanding the sheriff to compel the indictee to appear, by distraining him by the issues (the produce) of those lands, to appear. If the return to the *venire facias* shows that the indictee has no lands, process of *capias* issues.

Before any indictment is found, a party charged upon oath with treason or felony may be brought before a magistrate by virtue of a warrant issued for his apprehension by the same or some other magistrate of the district, and may by another warrant be committed to prison for trial, if upon the examination there appear to be grounds to suspect that the party is guilty. (11 & 12 Vict. c. 42.)

A bench warrant, as it is termed, may also be issued by the justices of assize when an indictment is found.

PROCESS-VERBAL (*Procès-verbal*) is a term derived from French jurisprudence, in which it signifies a memorandum or instrument drawn up and attested by officers of justice, containing a statement of the circumstances which have taken place upon the execution of a commission, upon an arrest, upon a precognition or preliminary examination of a party accused, or in the course of other legal investigations, and set forth in the order in which they have occurred. The term is now frequently applied to a contemporaneous detailed minute or note of any formal proceeding, though not occurring in the course of any legal inquiry: *ex. gra.*, a note of the discussions which are taking place during the negotiation of a treaty, &c.

PROCLAMATION. By the constitution of England, the crown possesses the exclusive prerogative of issuing proclamations; for although this authority is exercised by the lord mayor in the city of London, and by the heads of some other corporations in other cities, for certain limited purposes, it is always founded upon custom or charter, and consequently only exists in such cases by delegation from the crown.

The nature and objects of royal proclamations are various. In some instances they are merely an authoritative promulgation of matters of state, or of acts of the executive government which it is necessary that all persons should know, and upon notice of which, as presumed to be conveyed by a public proclamation, certain duties and obligations attach to subjects. Proclamations of the accession of a new king or a demise of the crown, and proclamations for reprisals upon a declaration of war with a foreign state, and for rendering coin current within the realm, are examples of this kind. Another class of proclamations consists of those which declare the intention of the crown to exercise some prerogative or enforce the execution of some law which may have been for a time dormant or suspended, but which a change of circumstances renders it necessary to call into operation. Thus the crown might, by a proclamation in time of war, lay an embargo upon shipping, and order the ports to be shut, by virtue of its ancient and undoubted prerogative of prohibiting any of its subjects from leaving the realm. Another, and by far the most usual, class of proclamations issued by the crown consists of formal declarations of existing laws and penalties, and of the intentions of government to enforce them, designed, as some of the early books term it, *quoad terrorem populi*, and merely as admonitory notices for the prevention of offences. A familiar instance of this kind of declaration is the proclamation against vice and immorality, appointed to be read at the opening of all courts of quarter-sessions.

At present the royal prerogative does not authorise the creation of an offence by proclamation which is not a crime by the law of the land. In early periods of our history after the Norman conquest, the power of the crown in this respect appears to have been much more extensive, and instances of proclamations may be found in Rymer's 'Fœdera,' and elsewhere, evincing an assumption of almost despotic authority by the crown. In the reign of Henry VIII. the king was enabled, with the advice of his council, to set forth proclamations under such penalties and pains as to him might seem necessary; but this was by Act of Parliament, and the statute was repealed about five years afterwards. A strenuous attempt was made in the reign of James I. to strengthen the crown by increasing the prerogative of making proclamations, which, though encouraged and promoted by the Lord Chancellor Ellesmere and Bacon, were resisted by Coke, and occasioned great alarm and dissatisfaction among the people. The encroachments which had been made and attempted in this respect are enumerated and complained of in the 'Petition of Grievances' by the Commons, in 1610 (Howell's 'State Trials,' vol. ii.); and in the same year it was expressly resolved by the judges (of whom Sir Edward Coke was one) that the king could not by his proclamation create an offence which was not an offence before; "for if so, he might alter the law of the land by his proclamation." (Coke's 'Reports,' part 12.)

PROCONSUL. [Consul; Provincia.]

PROCTOR, derived from the civil law term "procurator"—one that seeth after another man's affairs. It is the designation of those who in the Ecclesiastical and Admiralty courts (where the forms of the civil law prevail), conduct the business of their clients as attorneys and solicitors do in the courts of law and equity, but in order to enable them to act in the Ecclesiastical court, they must be formally authorised by a "proxy" from their clients to do so (129 s. Canon). Proctors also act as notaries public, in attesting acts and conducting proceedings in their own courts, but they do not possess the authority of notaries generally. In order to practise in the Ecclesiastical courts, they must be admitted by the archbishops of the respective provinces, by application to their vicar-general or official principal. In the Admiralty court they are admitted by the judge of the court.

The recent Acts of Parliament, however, the 20 & 21 Vict. c. 77 (the Act to amend the law relating to Probates and Letters of Administration), and the 20 & 21 Vict. c. 85 (the Act to amend the law relating to Divorce and Matrimonial Causes), have transferred to the temporal courts the jurisdiction of the Ecclesiastical courts over wills, intestacies, and divorce, and in so doing, the practice is no longer confined to proctors, but is thrown open to barristers attorneys, and solicitors. The 22 & 23 Vict. c. 6, also empowers barristers, attorneys, and solicitors, to practise in the court of Admiralty. Thus the practice in the testamentary and matrimonial business of the Ecclesiastical courts and that of the court of Admiralty is no longer confined to the advocates and proctors of Doctors' Commons. Marriage licences are obtained through the medium of proctors: they prepare the affidavit containing the particulars required to enable parties to be married without the publication of banns. The 5 Geo. II. c. 18, s. 2, prohibits practising proctors from being justices of the peace. But they are exempt from serving on juries, or being made parish officers, as churchwardens, &c. The term "proctor" is also applied to those of the clergy, who are selected by their brother clergy to represent them in convocation [CONVOCATION]. For the practice of the Ecclesiastical courts, see COURTS, ECCLESIASTICAL.

The two proctors in the universities of Oxford and Cambridge are nominated by each college in rotation from among the resident masters of arts. They hold office for a year; they each have two proproctors. Their office is of great dignity and importance; they rank after the vice-chancellor. Their duties are to preserve order and discipline among the under-graduates, and to aid the authorities in all their important functions.

PROCURATOR, a manager or agent, whence the word proctor is formed.

A Roman procurator was a person appointed by another to conduct a cause for him, and it required no particular words to constitute a procurator. A man might commence a suit as a procurator, without showing his authority; but he was obliged to produce it before the judges came to a decision, or to enter into security that the plaintiff would abide by his acts. (Gaius, iv. 84.)

Under the Empire the governor of a province was, in certain cases, called a Procurator, or Procurator Cæsaris. Sometimes this Procurator had not the government of a province, but only managed affairs of revenue (res fisci). [PROVINCIA.]

Solicitors in Scotland who practise in the courts of the Sheriffs, are usually called Procurators; and in judgments the courts generally recite the hearing of the Procurators of the parties.

Procurator Fiscal, in Scotland, is the term used to denote the public prosecutor.

PROCYON. [SIRIUS and PROCYON.]

PRODUCT, a term really equivalent to result, but used only when the result is the one obtained by the multiplication of two or more quantities.

PROFANENESS. [BLASPHEMY.]

PROFIT, one of the three parts into which all that is derived from the soil by labour and capital is distributed, the other two being wages and rent: from these three sources arise all the revenues of the community. Profit is therefore the surplus which remains to the capitalist after he has been reimbursed for the wages advanced and the capital expended during the process of production. To obtain this surplus is the only object for which capital is employed.

Profits have a tendency to fall to the same level in all branches of industry; for if the ratio of profit in proportion to the capital employed be greater in one than in another, more capital will be directed to that which affords the highest profit; and the powers of production being increased, the supply is greater, prices fall, and the equilibrium of profit is restored. A distinction must however be made between real and apparent profit. When the employment of capital is attended with extraordinary risk, profits are nominally high; but after deducting the losses to which it is exposed, the real profits tend to the same level as the ordinary rate. The case is similar in occupations of a disagreeable or agreeable nature, the pleasantness of the latter counterbalancing the low rate of profit. A wholesale merchant and a retail trader both dealing in the same commodities may appear to obtain different rates of profit; but in the latter case wages are confounded with profits, and when they are properly distinguished, the apparent disproportion is diminished. Unless we reduce profits from their apparent to their real value, there is no truth in the maxim that the rate of profit is uniform in the same country at the same time.

The natural tendency of profits (whether arising from capital employed in agriculture or in manufactures) is to decline as the necessities of the population render it necessary to have recourse to inferior soils. Happily, improvements in machinery and in the art of agriculture, better combinations of labour and capital, and greater freedom of commerce, are calculated to arrest this retrograde movement; and to such sources of relief every highly advanced country must look as a means of sustaining its prosperity; for whatever diminishes the necessity of raising food from the poorer soils, tends to maintain the rate of profit.

Two other causes have great influence upon the rate of profit, namely, wages and taxation. A rise in wages will diminish profits, unless industry becomes more productive; but if the latter take place, both may rise at the same time, either in the same or in different proportions according to circumstances.

Taxation will diminish profits, unless wages fall or industry become more productive. Taxes on profits, when they fall alike upon all capital engaged in productive industry, are paid by the owners of capital, who have not the power of charging the tax upon consumers. The means of accumulation are diminished when the profits of only certain classes of traders are taxed, and they would betake themselves to other occupations not taxed, unless they could charge the consumers with the tax: the tax therefore falls upon the consumers.

The competition of capitalists also acts in reducing the rate of profit, though this has been denied by some writers. Capitalists who have accumulated at the old rate of profit are content with a new investment producing a lower rate, instead of consuming their savings unproductively.

PROGNOSIS (in Medicine) is the opinion formed respecting the probable future events of any disease, as, for example, whether it will terminate in recovery or in death, how long it is likely to continue, what other diseases may be expected to arise in its course, what are the chances of relapse, and what those of some permanent injury of structure or function being produced by the morbid processes.

PROGRESSION. A series of numbers following any law should be called a progression, but the word is usually restricted to two sorts of progression, which are called, but by no means correctly, arithmetical and geometrical: the analogies pointed out in RECTANGLE give the origin of these terms.

An *arithmetical progression* is one in which the terms continually increase or diminish equally, including, as an extreme case, that in which they do not increase or diminish at all. Thus

$$\begin{array}{ll} 7,\ 7,\ 7,\ 7,\ \&c. & 7,\ 8,\ 9,\ 10,\ \&c. \\ 10,\ 9\tfrac{1}{2},\ 9,\ 8\tfrac{1}{2},\ \&c. & 2,\ 3\tfrac{1}{4},\ 4\tfrac{1}{2},\ 5\tfrac{3}{4},\ \&c. \end{array}$$

are sets of terms in arithmetical progression. The following proposition contains the principal part of their theory:—

If a be the first term of an arithmetical progression, and Δa the difference between any two terms (negative, if the terms diminish); and if a_n be the nth term from and after a *exclusive*, and s_n the sum of n terms, we have

$$a_n = a + n\,\Delta a\,;$$
$$s_n = na + n\,\frac{n-1}{2}\,\Delta a.$$

From these two equations between a, n, a_n, Δa, and s_n, any three of these being given, the other two can be found, subject however to this restriction, that the problem is unmeaning when n is not a whole number, whether it be given or found. These theorems are only the simplest case of a more general pair, in which, taking any series, and supposing neither the differences nor the differences of the differences, &c., to be equal, an expression is given for any term of a series, or for the sum of n terms, which frequently gives definite forms in the place of indefinite ones. Calculate, as in the article DIFFERENCE, the value of Δa, $\Delta^2 a$, &c., from a, a_1, a_2, &c., and let

$$n_1 = n,\ \ n_2 = n\,\frac{n-1}{2},\ n_3 = n\,\frac{n-1}{2}\,\frac{n-2}{3},\ \&c.$$

Then
$$a_n = a + n_1\,\Delta a + n_2\Delta^2 a + n_3\Delta^3 a +,\ \&c.$$
$$s_n = n_1 a + n_2\Delta a + n_3\Delta^2 a + n_4\Delta^3 a +,\ \&c.$$

Thus in the series 1 + 5 + 17 + 43 + 89 + 161 + &c., the law of whose terms is undiscoverable at first sight, we shall, by what the beginner may, till he knows better, call an accidental circumstance, discover both the law of the terms and that of their sum, as follows:—

$$\begin{array}{cccccc} 1 & & & & & \\ & 4 & & & & \\ 5 & & 8 & & & \\ & 12 & & 6 & & \\ 17 & & 14 & & 0 & \\ & 26 & & 6 & & 0 \\ 43 & & 20 & & 0 & \\ & 46 & & 6 & & \\ 89 & & 26 & & & \\ & 72 & & & & \\ 161 & & & & & \end{array} \qquad \begin{array}{l} a=1,\ \Delta a=4,\ \Delta^2 a=8, \\ \Delta^3 a=6,\ \Delta^4 a=0,\ \Delta^5 a=0, \\ \&c. \end{array}$$

$$a_n = 1 + 4n_1 + 8n_2 + 6n_3 = n^3 + (n+1)^2$$
$$s_n = n + 4n_2 + 8n_3 + 6n_4$$
$$= \left(n\,\frac{n-1}{}\right)^2 + \frac{n\,(n+1)\,(2n+1)}{6}$$

Thus the seventh term (the sixth after 1, $n=6$) is 6^3+7^2, or 265, and the sum of 6 terms (make $n=6$ in the second formula, in which remember that s^n is the sum of n terms, not of n terms after a) is $(\tfrac{1}{2}.6.5)^2+\tfrac{1}{6}.6.7.13$, or 316, which may easily be verified. [SUM.]

The apparently accidental circumstance above alluded to, is the vanishing of all the differences of a from and after the fourth. But it is to be observed, that the series was originally constructed so as to make all differences vanish after the fourth, and that the preceding theorem will never change indefinite into definite formulæ, except when all differences after a certain one vanish. The rule is, when a_n is an algebraically rational and integral function of n of the p order, that is, of the form $kn^p + ln^{p-1} +$, &c., all differences after the pth vanish, and then only.

Geometrical Progression is when the terms of a series increase or diminish by the use of the same multiplier, whole or fractional, including, as an extreme case, that in which the multiplier is unity.

Thus, the multipliers being 1, $\frac{8}{7}$, $\frac{1}{2}$, and 2, the four following sets of terms are in geometrical progression :—

$$7,\ 7,\ 7,\ 7,\ \&c. \qquad 7,\ 8,\ \tfrac{64}{7},\ \tfrac{512}{49},\ \&c.$$
$$3,\ \tfrac{3}{2},\ \tfrac{3}{4},\ \tfrac{3}{8},\ \&c. \qquad 9,\ 18,\ 36,\ 72,\ \&c.$$

If a be the first term, and b the second, the nth term is $a\,(b \div a)^{n-1}$, and the sum of n terms is

$$\frac{a^n - b^n}{a^{n-2}\,(a-b)} \quad \text{or} \quad \frac{b^n - a^n}{a^{n-2}\,(b-a)}$$

according as a is greater than or less than b. But when $a=b$, the sum is of course na. If $b \div a = r$, that is, if the terms be a, ar^2, ar^3, &c., the nth term is ar^{n-1}, and the sum of n terms is

$$a\,\frac{1-r^n}{1-r} \quad \text{or} \quad a\,\frac{r^n-1}{r-1},$$

according as r is less than or greater than one. If r be less than one, the series of terms, however far it may be carried, never reaches $a \div (1-r)$, though it may approach this limit with any degree of nearness by making the number of terms sufficiently great.

Thus the following equations,

$$2 = 1 + \tfrac{1}{2} + \tfrac{1}{4} + \tfrac{1}{8} + \tfrac{1}{16} + \&c.$$
$$1 = \tfrac{2}{3} + \tfrac{2}{9} + \tfrac{2}{27} + \tfrac{2}{81} + \tfrac{2}{243} + \&c.$$

though always erroneous, stop where we may, yet can be brought as near to truth as we please by writing down terms enough on the second side. In the use of the word INFINITE, as explained in the article on that subject, we may then say that the above equations are absolutely true, if the series be carried *ad infinitum*. The general equation, made absolutely true, after stopping at ar^n in the series, is

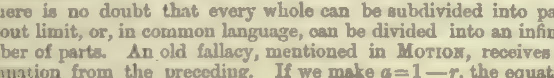
$$\frac{a}{1-r} = a + ar + \ldots + ar^n + \frac{ar^{n+1}}{1-r}.$$

Other points connected with this equation will be mentioned in the article SERIES.

There is no doubt that every whole can be subdivided into parts without limit, or, in common language, can be divided into an infinite number of parts. An old fallacy, mentioned in MOTION, receives its explanation from the preceding. If we make $a = 1 - r$, the equation carried *ad infinitum* becomes

$$1 = (1-r) + (1-r)\,r + (1-r)r^2 + ,\ \&c.,\ ad\ inf.$$

By giving different values to r, we have therefore an infinite number of ways of subdividing unity into an infinite number of parts. If then we take a problem in which an antecedent is followed by a consequent; and if dividing the antecedent into an infinite number of parts, we consider separately the parts of the consequent which belong to those of the antecedent, we shall of course divide the consequent into an infinite number of parts. It would be a gross fallacy to infer that the consequent must be infinitely great, because it is produced in a never-ending succession of parts, since that never-ending succession was produced by dividing the avowedly finite antecedent into an infinite number of parts. No one could fail to detect the following :—"Let M be divided into an infinite number of parts, a, b, c, &c.; let each of these parts be doubled; then the result is made up of $2a$, $2b$, $2c$, &c., *ad infinitum*; consequently $2a+2b+2c+$, &c., being made up of an infinite number of quantities, is infinite." Nevertheless this fallacy was not only produced in an ingenious form, as a sophism [MOTION], but has even reappeared in modern times as a serious argument. The sophism is known by the name of "Achilles and the Tortoise." The swiftest of men runs after the slowest of beasts, without (says the sophism) the possibility of ever overtaking it. For if, when they set out, Achilles be at A and the tortoise at T, then by the time Achilles has run over AT, how fast soever he may run, the tortoise will have gone over some length, say TB; while the hero goes over TB, his dinner (for dinner he may have out of it, in spite of the sophism) goes over BC, and so on *ad infinitum*. How then, asks the objector, is it possible that Achilles can ever come up with the tortoise, since it is unquestionable (and this is perfectly correct), that let him go as far as he may, he must always come up to where the tortoise was before he can reach the point at which he is; so that it requires *an infinite number of parts of time* (but here the sophism quietly introduces *an infinite time*) to catch the tortoise? The answer is, that Achilles will certainly overtake the tortoise at a finite distance from A, say at M: any contrivance which subdivides A M into an infinite number of parts, does the same with the time in which Achilles runs over A M; and there is no more reason to say that the time is therefore infinitely great, than to say that A M is made infinitely great by the subdivision. This would be a sufficient answer, since it would throw upon the sophist the *onus* of showing that the infinite number of parts of time makes an infinite time; but a more complete answer consists in positive proof that it is not so, as follows :—



Let A T be called a, and let Achilles move m times as fast as the tortoise; then T B is necessarily the mth part of A T, B C of T B, C D of B C, &c. Hence, if t be the time in which Achilles moves over A T, this time, added to his times of going over T B, B C, C D, &c., or t, $t \div m$, $t \div m^2$, &c., make up

$$t\left(1 + \frac{1}{m} + \frac{1}{m^2} + \frac{1}{m^3} + \frac{1}{m^4} + ,\ \&c.,\ ad\ inf.\right)$$

Now if m be greater than 1 (for unless Achilles move faster than the tortoise, it is admitted he can never catch it), the series above named is $1 \div \left(1 - \frac{1}{m}\right)$, so that the whole time is $tm \div (m-1)$, and the whole length A M is $am \div (m-1)$, the same answer as would be produced by common methods. The sophism divides this length into the infinite number of parts

$$a \qquad \frac{a}{m} \qquad \frac{a}{m^2} \qquad \frac{a}{m^3} \qquad \&c.$$

and taking the times due to each,

$$t \qquad \frac{t}{m} \qquad \frac{t}{m^2} \qquad \frac{t}{m^3},\ \&c.,$$

assumes the sum of the latter to be infinite.

In the work of a celebrated political economist there is the following argument, to show that a tax on wages must fall on the labourers; for if it did not so fall, wages would rise, whence the price of goods would rise, which would again cause a rise of wages, and this again a rise in goods, and so on *ad infinitum*, which is inferred to be absurd. This is of course precisely a repetition of the preceding case; and granting all the premises, the conclusion by no means follows. For that conclusion is that the rise would go on without limit, which need not be the case.

The best way of remembering the summation of a geometrical series is by a verbal rule, as follows :—The sum is the difference between the first term *in* and the first term *out*, divided by the difference between the common multiplier and unity. Thus the sum of 30 + 90 + 270 + 810 is 2430 — 30 divided by 3 — 1, or 1200.

PROHIBITION, a writ to prohibit a court and parties to a cause then depending before it from further proceeding in the cause. It will be convenient to define,—1, out of what courts it issues; 2, to what courts it may be addressed; 3, under what circumstances it is grantable; 4, at whose instance it may be obtained; 5, at what time it may be obtained; 6, the form and incidents of the proceeding.

1. A writ of prohibition usually issues from one of the three superior courts of common law at Westminster. It may issue from the Common-Law Court at Lancaster, and from the common-law side of the Court of Chancery.

2. It may be addressed to any other temporal court, such as to the Admiralty Courts, to Courts-Martial, to any inferior court in a city or borough, to the Duchy or County Palatine Courts, to the Stannary Courts, to the Commissioners of Appeals of Excise, to any court by usurpation without lawful authority, or to a court whose authority has expired. When any one has a citation to a court out of the realm, a prohibition lies to prevent his answering. It seems also that it might issue to the Court of Exchequer, and to the Court of Common Pleas; but not to the Court of Chancery; nor is there any instance of a prohibition to the King's Bench. It may be granted by any of the three superior common-law courts to any spiritual court, and by the common-law courts of Chester and Lancaster to the spiritual courts within the county palatine and duchy.

3. The writ is grantable in all cases where a court entertains matter not within its jurisdiction; or where, though the matter is within its jurisdiction, it attempts to try by rules other than those recognised by the law of England. Matter may be said to be not within the jurisdiction of a court in two senses: 1, when the subject-matter entertained is in its nature not cognisable by the court; 2, where the subject-matter is in its nature cognisable by the court, but lies out of the local district where only that court has jurisdiction; or, in the case of a court whose jurisdiction is general, when the subject-matter lies in a local district exempt from the general jurisdiction of the court, or where the subject-matter of the cause relates to persons over whom the court has no jurisdiction.

A prohibition will lie—to the courts of Admiralty, if they entertain questions of a contract made or to be executed within the kingdom; to the county court, if an action be brought in it on a judgment in one of the superior courts; to a spiritual court, if it takes cognisance of any plea concerning a title to an advowson, or an office, or goods, money, or chattels; and this applies even in the case of goods or ornaments given to a church, or matters of a criminal nature punishable only temporarily: in short, as it has been said, anything for which a remedy exists at common law.

Prohibition lies equally both where the matter of the suit is not cognisable by the court, and where, though the substance is cognisable, matter arises during the progress of it, and is clearly about to be tried, over which the court has no cognisance. Thus, if in a cause properly cognisable by a spiritual court, a question arises, and is necessarily about to be tried, as to the existence of a custom, or a prescription, or the limits of a parish, or where in a suit for tithes there is plea of a modus, or that the lands are discharged by statute, or tithes are claimed of things for which no tithes are due, or the defendant makes title by lease, &c., a prohibition will lie immediately. And a prohibition is in all cases grantable where a court allows illegal or disallows legal evidence, as where the Commissioners of Appeals for the Excise determine by the minutes of evidence taken by a justice of the peace, instead of examining the witnesses *vivâ voce*, or a spiritual court disallows proof of payment, &c., because proof of it is made only by a single witness, or where it has misconstrued an Act of Parliament, or disallows an award when it is good by law.

A prohibition will also lie where a court attempts to extend its jurisdiction to parties over whom it has none, as where a court-martial inquires into the conduct of a person not a soldier or sailor; the Stannary courts, where neither parties are tinners, nor the matter in question respecting tin, &c.

4. A prohibition may be obtained at the instance of either party to an ecclesiastical suit. In the case of a suit for tithes against a lessee it may be obtained by the reversioner. Where a court has no jurisdiction over the matter of the suit, a prohibition is grantable at the request of a mere stranger.

5. If a court has no cognisance of the matter of a suit, prohibition will lie immediately after appearance, and it may be obtained by either plaintiff or defendant at any future time, even after sentence, appeal, and affirmation; or after judgment and execution, provided it appears by the proceedings that the court had no jurisdiction. When the court has cognisance of a cause, prohibition will not lie until the matter out of its jurisdiction has not only arisen, but is also clearly in progress of being tried. If the matter is then admitted by the litigant parties, the court is still entitled to certain cognisance of the suit. If not admitted, and these circumstances, though not appearing on the face of the proceedings, are duly brought forward before judgment, a prohibition will then lie. If, however, a prohibition is not then applied for, but the party submit to the trial in the court where the suit has been commenced and judgment is pronounced, no prohibition will lie unless it appear on the proceedings, not only that matter out of the jurisdiction of the court has arisen, but also that the matter has been wrongly decided. These observations only apply to permanent courts, and where something still remains to be done. In the case of an occasional court, as a court-martial, it would be impossible to carry the principle into execution.

6. A writ of prohibition is applied for by motion in court, which sets out the proceedings in the suit. If the proceedings are not sufficient to show the want of jurisdiction in the court against which prohibition is prayed, suggestions must be added, verified by affidavit, showing such want of jurisdiction.

If the court grants a rule, the other party is heard in answer. The court may then decide, either to refuse the prohibition, or, if they incline to grant it, direct the party applying to declare in prohibition. The declaration must contain a concise statement of the grounds of the application, and conclude by praying that the writ may issue. To this the other party may demur on the ground that no sufficient cause appears for a prohibition, or he may plead such matters as he thinks proper to show that the writ ought not to issue, and conclude by praying that it may not issue. If matters of fact are put in issue, they are tried by a jury. Judgment is given either on the demurrer or after nonsuit or verdict. The party succeeding is entitled to the costs of these proceedings, and, if a trial takes place, the jury may assess damages. If the court decide in favour of the party applying, the writ issues and forbids the court and other party from further proceeding. In such cases, if the ground of application was that the court had no jurisdiction at all in the suit, the writ of prohibition is final. But if the ground is that something had arisen not cognisable by the court, during the progress of a suit, concerning a matter properly within its jurisdiction, the prohibition is not final. In such case the question is referred to the proper tribunal for trial, and if found against the applicant, the suit may be then resumed. In either case, where the court decides in favour of the party against whom prohibition is prayed, or the verdict has been afterwards in his favour, the court awards a consultation, as it is called, by which the cause is again remitted to the original court. If parties proceed after a writ of prohibition has been obtained and served, they are liable to an attachment for contempt. No prohibition for the same matter lies after a consultation has been awarded upon the merits.

There can be no pleadings in a prohibition to the County Courts, the merits of which must be determined on the application for the writ.

(Comyns's *Digest*; 2 *Inst.*, 599; 3 Blackst. *Com.*, Mr. Kerr's ed., c. 7.)

The right of the common-law courts to issue writs of prohibition, and the mode in which they exercised that right, have often been the subject of great dispute between the common-law judges and the ecclesiastics. The latter have several times exhibited many articles of grievance before the parliament and privy council against the former. The most famous of these are the 'Articuli cleri,' exhibited by Archbishop Bancroft, in the name of the whole clergy, in the third year of the reign of James I. They are given at length by Lord Coke (2 'Inst.,' 599), with a full view of the nature of the controversy between the parties and the unanimous answers of the judges.

PROJECTILES, THEORY OF. This subject usually comprehends the investigation of the relations between the space described, the time of motion, and the velocity acquired by a body when impelled in any direction by some motive force.

The circumstances of a body descending from a high place towards the earth by the action of gravity, and those of a body projected vertically upwards from the earth, on the supposition, in both cases, that the body moves in a non-resisting medium, have been noticed in the article FALL OF BODIES; and the circumstances attending the motion, both in a resisting and a non-resisting medium, of a body impelled by fired gunpowder, when the impulse is in a direction parallel or oblique to the horizon, have been investigated in the article GUNNERY. It is intended therefore in this place only to consider the laws of the vertical ascent and descent of bodies in resisting media, the force of gravity, or of terrestrial attraction, being supposed to be constant; and in non-resisting media, under the condition that the force of gravity is variable.

Let a spherical body descend vertically from a state of rest in a resisting medium (air, water, &c.) supposed to be of uniform density; and let it be admitted, agreeably to the Newtonian hypothesis ('Princip.', lib. ii. sec. 1; *Schol.*), that the resistance of the medium is proportional to the square of the velocity, v, acquired at any moment in the descent; then, if we suppose U to be the velocity which a body falling towards the earth in the resisting medium would acquire when that resistance becomes equal to the accelerative force of gravity, the latter being, as usual, represented by g $(=32{\cdot}2$ feet), we shall have $\mathrm{U}^2 : g :: v^2 : \frac{v^2}{\mathrm{U}^2}g$; and the last term represents the resistance of the medium at the instant when the velocity is v; hence the accelerative force by which the falling body is urged at such moment is expressed by $g - \frac{v^2}{\mathrm{U}^2}\,g$.

Now s being the space descended by the body in the time t, and v being the velocity as before, an accelerative force is represented by $\frac{d\,v}{d\,t}$ and by $\frac{d^2\,s}{d\,t^2}$. [FORCE.] Therefore $\frac{d\,v}{d\,t} = g - \frac{v^2}{\mathrm{U}^2}g$; whence $gdt = \frac{dv}{1 - \frac{v^2}{\mathrm{U}^2}}$; and integrating this equation, observing that $v = 0$ when $t = 0$, we have $t = \frac{\mathrm{U}}{2g}$ hyp. log. $\frac{\mathrm{U}+v}{\mathrm{U}-v}$, or $\frac{2gt}{\mathrm{U}} =$ hyp. log. $\frac{\mathrm{U}+v}{\mathrm{U}-v}$; or again, passing from logarithms to numbers, $\frac{\mathrm{U}+v}{\mathrm{U}-v} = c^{\frac{2gt}{\mathrm{U}}}$ (c being the base of the hyperbolic logarithms); whence $v = \mathrm{U}\frac{c^{\frac{2gt}{\mathrm{U}}} - 1}{1 + c^{\frac{2gt}{\mathrm{U}}}}$, and this second member being developed, gives $v = gt - \frac{g^3t^3}{3\mathrm{U}^2} + \&c.$ Substituting, in this equation, $\frac{ds}{dt}$ for v, and again integrating, we have $s = \frac{1}{2}\,gt^2 - \frac{g^3t^4}{12\mathrm{U}^2} + \&c.$

These equations for s and v give the space descended and the velocity acquired at the end of any given time t from the moment when the motion commenced. For tables of the values of U (the terminal velocities) for iron balls, see Dr. Hutton's Tracts, tract 37.

Next, let a body be projected vertically upwards in a uniformly resisting medium with an initial velocity $= \mathrm{V}$; and let the body be of a spherical form so that U may be the same as before: then, the force of gravity and the resistance of the medium acting in a direction opposite to that of the projectile force, we have now $\frac{dv}{dt} = -g - \frac{gv^2}{\mathrm{U}^2}$; whence $-gdt = \mathrm{U}\frac{d.\,\frac{v}{\mathrm{U}}}{1 + \frac{v^2}{\mathrm{U}^2}}$. This equation, being integrated, gives $-gt = \mathrm{U}$ arc tan. $= \frac{v}{\mathrm{U}} + const.$; and considering that $v = \mathrm{V}$ when $t = 0$, the constant is equal to $- \mathrm{U}$ arc tan. $= \frac{\mathrm{V}}{\mathrm{U}}$; putting $-\mathrm{C}$ to represent this term, we have $\frac{\mathrm{C} - gt}{\mathrm{U}} =$ arc tan. $\frac{v}{\mathrm{U}}$; and passing from arcs to tangents, we have $\frac{v}{\mathrm{U}} =$ tan. $\frac{\mathrm{C} - gt}{\mathrm{U}}$, or $v = \mathrm{U}$ tan. $\frac{\mathrm{C} - gt}{\mathrm{U}}$. Multiplying both members of the last equation by dt, and putting dx for its equal vdt, this equation becomes $dx = \mathrm{U}$ tan. $\frac{\mathrm{C} - gt}{\mathrm{U}}\,dt$; which integrated gives $x = \frac{\mathrm{U}^2}{g}$ hyp. log. cos. $\frac{\mathrm{C} - gt}{\mathrm{U}} + const.$ The constant is determined by considering that $x = 0$ when $t = 0$; whence *const.* $= -\frac{U^2}{g}$ hyp. log. cos. $\frac{c}{U}$: therefore $x = \frac{U^2}{g}$ hyp. log. $\dfrac{\cos.\ \frac{c-gt}{U}}{\cos.\ \frac{c}{U}}$

Making $v = 0$ in the above equation for v, we get the value of t when the body has attained its greatest height; and substituting the value of t so found in the last equation for x, we have that greatest height.

When arrived at the greatest height, the body would begin to return towards the earth; and it may be shown that the velocity acquired by the body on arriving at the place from whence it was projected would be less than the initial velocity; also that the time of the descent would differ from the time of ascent.

If we imagine the earth to be perforated in the direction of a diameter; and if a body be allowed to descend towards the centre in a non-resisting medium from any point in the line of perforation: the law of attraction being in such a case directly proportional to the distance of the body at any time from the centre of the earth (Newton, lib. i. prop. 73), the relation between the space descended and the time of descent may be thus investigated.

Let r be the radius of the earth, and let the force of gravity at the surface be represented by g; then x being any distance from the centre, the attracting force acting on the body at that distance will be $\frac{gx}{r}$. Therefore since the distance of the body from the centre diminishes, while the time reckoned from the moment of departure increases, we shall have $\frac{d^2x}{dt^2} = -\frac{gx}{r}$. This equation will be found to be verified by assuming $x = a \cos. t\sqrt{\frac{g}{r}} + b \sin. t\sqrt{\frac{g}{r}}$; which being differentiated once, gives $\frac{dx}{dt} = -a\sqrt{\frac{g}{r}} \sin. t\sqrt{\frac{g}{r}} + b\sqrt{\frac{g}{r}} \cos. t\sqrt{\frac{g}{r}}$. Now, in the equation for x, making $x = r'$ (any given distance from the centre) when $t = 0$, we have $a = r'$; and in the equation for $\frac{dx}{dt}$, making $\frac{dx}{dt}$ (the velocity) $= 0$ when $t = 0$, we have $b = 0$. Consequently $x = r' \cos. t\sqrt{\frac{g}{r}}$; whence x is found when t is given: but when $x = 0$, we have $t\sqrt{\frac{g}{r}} = \frac{\pi}{2}$ (where π represents the half circumference of a circle whose radius is equal to unity) whatever be the value of r'. Therefore $t = \frac{\pi}{2}\sqrt{\frac{r}{g}}$ will express the time of falling from the surface to the centre of the earth.

Let it now be required to investigate the relations between the times, the spaces described, and the acquired velocities when a body falls in vacuo from a point at such a distance from the earth that the attraction of gravity upon it may be considered as variable; and when, agreeably to the law of nature, its intensity is inversely proportional to the square of the distance. ('Princip.,' lib. i., prop. 74.) Then, if r be the radius of the earth, p the distance from the centre of the earth to the point above the latter from whence the body is let fall; and if x be the space descended in any time t: also if g be the force of gravity at the earth's surface, we shall have $\frac{1}{r^2} : g :: \frac{1}{(p-x)^2} : \frac{r^2 g}{(p-x)^2}$; and the last term expresses the force of gravity at the place of the body when the space descended is x and the time of descent is t: therefore $\frac{d^2x}{dt^2} = \frac{gr^2}{(p-x)^2}$.

In order to integrate this equation, multiply both sides of it by $2dx$; and then the first integral will be $\frac{dx^2}{dt^2} = \frac{2gr^2}{p-x} + \textit{const.}$ The constant may be found on considering that $\frac{dx}{dt}$ (the velocity) $= 0$ when $t = 0$, when also $x = 0$; therefore *const.* $= -\frac{2gr^2}{p}$, and $\frac{dx^2}{dt^2} = 2gr^2\left(\frac{1}{p-x} - \frac{1}{p}\right)$; whence $\frac{dx}{dt} = \sqrt{\left\{\frac{2gr^2}{p} \cdot \frac{x}{p-x}\right\}}$. This equation may be put in the form $\frac{(p-x)\,dx}{\sqrt{px-x^2}} = \frac{2gr^2}{p}\,dt$; and by the rules of integration we have $t\sqrt{\frac{2gr^2}{p}} = \sqrt{px-x^2} + \frac{1}{2}p \text{ arc cos.} = \frac{p-2x}{p}$: there is no constant to be added, because $x = 0$ when $t = 0$. From this equation t may easily be found when x is given: likewise from the equation for $\frac{dx}{dt}$ we have the velocity when x is given. And if x be made equal to $p-r$, the whole distance of the body from the surface of the earth, we shall obtain the whole time of the descent and the velocity acquired at the end of that time.

Again: let it be supposed that a body may be projected vertically upwards in vacuo from the surface of the earth, and be subject to a variably accelerative force of attraction downwards. Let r be the semidiameter of the earth as before; and now let x be the height ascended from the surface at the end of the time t: also let h be the height due to the initial velocity, supposing the latter to have been acquired by a body falling in vacuo with a uniformly accelerative force; then $2gh$ will express the square of that velocity. By the law of attraction we have $\frac{1}{r^2} : g :: \frac{1}{(r+x)^2} : \frac{gr^2}{(r+x)^2}$; and the last term expresses the intensity of the attractive force at the end of the time t from the commencement of the ascent. Hence $\frac{d^2x}{dt^2} = \frac{gr^2}{(r+x)^2}$.

In order to integrate this equation, multiply both sides by $2dx$; then we get $\frac{dx^2}{dt^2} = -\frac{2gr^2}{r+x} + \textit{const.}$: and to find the constant, it must be observed that $x = 0$ when $\frac{dx^2}{dt^2} = 2gh$; therefore *const.* $= 2g(h+r)$ and $\frac{dx^2}{dt^2} = 2g(h+r) - \frac{2gr^2}{r+x}$, or $= \frac{2g\{hr+(h+r)x\}}{r+x}$. Taking the square roots and transposing, we have $\frac{\sqrt{r+x}}{\sqrt{\{hr+(h+r)x\}}}\,dx = \sqrt{2g} \,.\, dt$, and this equation may be put in the form

$$\frac{(r+x)dx}{\sqrt{\{hr^2+(2h+r)rx+(h+r)x^2\}}} = \sqrt{2g} \,.\, dt;$$

or (h being small compared with r) rejecting h when added to r, the equation becomes

$$\frac{(r+x)dx}{\sqrt{\{hr^2+r^2x+rx^2\}}} = \sqrt{2g} \,.\, dt.$$

Now, multiplying the numerator and denominator of the first member by $2r$, and putting the whole in the form

$$\frac{(r^2+2rx)dx}{2r\sqrt{\{hr^2+r^2x+rx^2\}}} + \frac{r\,dx}{2\sqrt{\{hr^2+r^2x+rx^2\}}} = \sqrt{2g} \,.\, dt,$$

the rules of integration give

$$\frac{1}{r}\sqrt{\{hr^2+r^2x+rx^2\}} + \frac{\sqrt{r}}{2}\text{ hyp. log.}\left\{\frac{r^{\frac{3}{2}}}{2} + x\sqrt{r} + \right.$$
$$\left.\sqrt{\{hr^2+r^2x+rx^2\}}\right\} + \textit{const.}\ \sqrt{2g}\ \ t.$$

The constant may be determined by considering that $x = 0$ when $t = 0$; and thus t may be found when x is given.

What has been stated respecting the vertical descent and ascent of bodies may be understood to apply also to bodies descending and ascending on inclined planes; the force of gravity on the plane being represented by g sin. a, where a is the inclination of the plane to the horizon.

In Dr. Hutton's Tracts there is given a problem for determining the height ascended by a ball when projected vertically upwards with a given velocity, and resisted by the air; the force of gravity being supposed to be constant, and allowance being made for the decrease in the density of the air as the ball ascends. (Tract 37, prob. v.) In the same tract there is also given (prob. xi.) an investigation of the circumstances attending the motion of a body in air when projected horizontally on a smooth surface so that the action of gravity may produce no effect on the motion of the body, the resistance varying as the square of the velocity. Also in Poisson's 'Traité de Mécanique,' the following remarkable circumstance is demonstrated:—If a body be projected, as in the last case, and if the resistance of the air vary as the square root of the velocity; the motion of the body will at first diminish gradually till it becomes equal to zero; and afterwards it will go on increasing indefinitely. ('Tom.' i., no. 136, ed. 1833.) But for the demonstrations of these problems our limits oblige us to refer the reader to the works just mentioned.

PROJECTION. The practical parts of this most important application of geometry are noticed in the articles MAP; PERSPECTIVE; GNOMONIC; GLOBULAR; ORTHOGONAL, ORTHOGRAPHIC; STEREOGRAPHIC; &c. The present article is merely intended to point out the general principle of all projections, and also to note the theoretical importance of the subject.

Imagine a surface of any kind, through every point of which passes a curve the character of which depends upon that point, insomuch that, given a point of the surface, the curve which passes through that point is given in character and position. If any second surface be taken, which is cut by all the curves emanating from the points of the first, every point of the first surface has a point corresponding to it on the second. Thus if the curve passing through A on the first surface cut the second surface in a, the point A is said to be projected on the second surface at a by means of the projecting curve A a. Similarly any line on the first surface is projected into a line on the second, which last contains the projections of all the points on the first; and the projections of the several boundaries of a figure on the first surface are boundaries of a figure on the second, which is the projection[*] of the first figure.

It is perhaps not usual to make so wide a definition of projection in general, since the only cases which are commonly considered are those in which the projecting lines are all straight, and either parallel to one another, as in the orthographic projection, or all passing through the same point, as in common perspective. But such a conception of projection is necessary: in Mercator's projection, for example, [MAP] the points of a sphere are projected on a circumscribing cylinder, not by straight lines passing through a point, but either by straight lines disposed according to a complicated law, or else by curves. If a relation between any point and its projection be given, so that either can be found from the other, the passage from one to the other may be made either on a straight line or on an infinite variety of curves; but it may happen that the law which the disposition of the projecting straight lines follows may be of a more difficult character than that which would be required if a curve, not in itself so simple as a straight line, were substituted.

When the foundations of plane geometry were fixed, and the first principles of solid geometry were superadded, it was natural that the very simple idea of the perspective projection should excite attention. In a country in which the first principles at least of drawing were practically known, the following problem must have suggested itself to the geometers: If through a given point lines be drawn through all the points of the boundary of a plane figure, until they are stopped by another plane, required the figure traced out upon the second plane. A straight line was known thus to give a straight line: a moment's consideration of the circle, the only other line then considered, would show that a projection of a circle and a plane section of a cone are the same things. Hence probably the first idea of a conic section; and thus, if the conjecture be correct, the attention was turned from that point, which would, if properly kept in view, have led to the theory of projections in place of one isolated branch of it. The properties of the conic sections, as deduced in the ancient manner from the cone, are neither so general nor so easy as they might be made; and it may be confidently expected, considering the progress which the doctrine of projections has made of late years, that the method of considering the ellipse, hyperbola, and parabola as projections of the circle, will become established in elementary teaching, in preference to the detached geometrical and algebraical methods now in use.

We have already spoken of the geometry of projections [GEOMETRY]: unfortunately there is no elementary work which gives a general view of its first principles supported by sufficient application; and until such a work shall appear, the student must search for himself the writings of Monge, Carnôt, Chasles, Poncelet, &c. The 'History of Geometry,' by M. Chasles, referred to in the article cited, will furnish many more references; and the 'Propriétés Projectives des Figures,' by M. Poncelet, is perhaps the work in which the student may most easily make an advantageous beginning of the subject. Much has been done of late years to introduce some elements into works on the conic sections: but projection has not yet been properly treated as a distinct subject.

The basis of the theory of projections must be the investigation of properties which, being true of a figure, are therefore true of its projections. Some of these are evident enough: thus the projection of an intersection of two lines is the intersection of their projections; if two curves touch one another, their projections touch at a point which is the projection of the point of contact. But the following property, which is projective, that is, true of the projections of every figure of which it is true in the first instance, will give a good idea of the facility with which certain properties of the conic sections may be deduced from the circle.

Let there be any figure in which the product of certain straight lines is equal to, or in any absolutely given ratio to, the product of certain others, each line being denoted by an initial and terminal letter in the usual way. We might say, in more geometrical language, let there be any number of ratios which, compounded together, give either a ratio of equality or a given ratio. Two simple conditions being fulfilled, this property will be as true of the projections as it is of the figure itself. These conditions are, first, that every initial and terminal letter shall occur the same number of times on both sides of the equation; secondly, that for every line on the first side, there shall be a distinct line on the other side, which is in the same straight line. For example (the reader may draw the diagram for himself), let each of the sides of the triangle ABC cut one circle, namely, AB in P and Q, BC in R and S, CA in T and V; the order of the points being APQBRSCTVA. Then by the properties of the circle, it is easily seen that

$$\mathrm{AV.\,AT.\,CS.\,CR.\,BQ.\,BP = AP.\,AQ.\,BR.\,BS.\,CT.\,CV.}$$

In this equation, A, B, and C occur twice on each side, and each of P, Q, R, S, T, V, once. Moreover, out of AB there are two segments, AP and AQ, on the first side, and as many, BQ and BP, on the second; and the same of BC and CA. He then who is acquainted with the theory of projections, immediately knows that this property is true of any projection of a circle, or of any conic section: but he would be an energetic algebraist who should attempt to prove this (or still more the equally demonstrable similar property in the case of a polygon of n sides) by the common algebraic methods.

The proof of the preceding general *projective* property is not difficult. Take a point O outside the plane for the centre of projection, and let $\mathrm{OA} = a$, $\mathrm{OB} = b$, &c.; moreover let the angle made by a and b be called (ab). Let A′, B′, &c., be the projections of A, B, &c., let $\mathrm{OA'} = a'$, $\mathrm{OB'} = b'$, &c., and let $(a'b')$ be the angle of a' and b', which is $= (ab)$. Moreover let [AB] mean the perpendicular let fall from O upon AB, &c. It is then easily proved that

$$\mathrm{AV} = \frac{a\,v.\ \sin\,(av)}{[\mathrm{AV}]},\quad \mathrm{AT} = \frac{a\,t.\ \sin\,(at)}{[\mathrm{AT}]},\ \text{\&c.}$$

Substitute these values in the equation, and it will be readily seen that the existence of the two conditions above named amounts to all the quantities except the sines of the angles being eliminable by division. There remains then

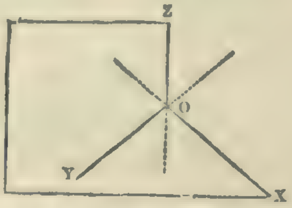
$$\begin{aligned} \sin\,(av).\ \sin\,(at).\ \text{\&c.} &= \sin\,(ap).\ \sin\,(aq).\ \text{\&c.} \\ \text{or } \sin\,(a'v').\ \sin\,(a't').\ \text{\&c.} &= \sin\,(a'p').\ \sin\,(a'q').\ \text{\&c.} \end{aligned}$$

In this write a', b', [A′V′], &c., where there were previously a, b, [AV], &c., which will amount (by the conditions) to multiplying both sides by the same quantities: there will then remain an equation which is obviously

$$\mathrm{A'V'.\,A'T'.}\ \text{\&c.} = \mathrm{A'P'.\,A'Q'.}\ \text{\&c.},$$

and in the same way any other case may be proved.

PROJECTION OF MATHEMATICAL DIAGRAMS. The diagrams by which mathematical students (and even writers) represent their solid figures are generally so imperfect, that it may be worth while to explain how, in all cases of sufficient importance, a good drawing may be made with very little trouble. The demonstration may be found in the 'Cambridge Mathematical Journal,' No. 8, p. 92. The projection is supposed to be the ORTHOGRAPHIC, in which the eye is at an infinite distance, and all parallels are projected into parallels, &c.



Let OX, OY, OZ, be the intended projections of the three axes of co-ordinates, the dark lines being supposed to belong to that quarter of space in which lies a line drawn to the eye from the origin O. Each of the angles YOZ, ZOX, XOY, is then greater than a right angle. The following table contains numbers sufficiently near for the purpose, proportional to the square roots of the sines of twice the angles written in the opposite columns.

---

[*] The projection of a line or figure has seldom any other name; in astronomy however, the projection of a planet's distance from the sun on the plane of the ecliptic is sometimes called the *curtate* distance.

The lines between the degrees are to be understood as representing half degrees: thus opposite to 991 should come 129½°—140½°. The use of this table is as follows:—suppose the angles Y O Z, Z O X, X O Y, to be severally 123°, 104½°, and 132½°: thus:—

Y O Z=123°	956	*x*
Z O X=104½°	696	*y*
X O Y=132½	998	*z*

Opposite to the angles put down the numbers belonging to them in the table, and opposite to each number the co-ordinate whose capital letter does not appear in the angle. Then opposite to *x*, *y*, and *z*, we have 956, 696, and 998. These numbers show the proportions which the projections of equal lines bear to one another on the three axes. Thus a foot parallel to *x* is to a foot parallel to *y*, as 956 to 696 in the projection. If then a card be taken, and the angle Z O X be cut out; and if a slit be made in the direction of O Y, just wide enough to permit a pencil to travel, scales of equal parts may be laid down on O X, O Y, and O Z, which shall represent the projections of equal lines in the three directions; and this may be done once for all. It would be easy enough to make a general scale by which the equal parts proper for any angle should be taken out at once.

The isometrical perspective of Professor Farish [Perspective, col. 416] is the simplest case of this, namely, that in which the angles are each 120°. The only difference between this particular case and any other is, that the former requires only one scale of equal parts, whereas the latter requires either two or three. In other respects this method of using them is precisely the same.

PROJECTION OF THE SPHERE, SHADOWS, &c. [Perspective.]

PROLOCUTOR. [Convocation.]

PROLOGUE (*πρόλογος*, from *πρὸ*, *before*, and *λόγος*, *speech*), is usually applied in English to the short poem or verses, which are sometimes prefixed to new plays to recommend them to the favour of the reader or spectators. In the comedies of Plautus and Terence we find prologues of this kind. Aristotle (' Poetik.' c. 12), gives the name of prologue to that part of the Greek tragedy which precedes the parodos, or first speech of the chorus.

PROMETHEUS (Προμηθεύς). The story of Prometheus takes different forms in the Greek legends, but they agree generally in representing the close connection between him and the human race. He is represented by Æschylus as one of the Titans, who incurred the resentment of Zeus for taking the part of mortals when Zeus intended to crush them and to send them to the abode of Hades, and also for giving them fire and teaching them all the arts. As a punishment, Zeus binds him to a rock in Scythia, and appoints a vulture to prey on his liver. This is the subject of the 'Prometheus Desmotes,' or 'Prometheus Bound,' of Æschylus.

Another old form of the legend, which closely resembles that which Æschylus followed, is given in the 'Theogony' of Hesiod. Hesiod says that when the gods and men were engaged in a controversy with one another at Mecone (an ancient name of Sicyon), Prometheus, wishing to deceive Zeus, took an ox, and dividing it, placed the flesh and the viscera in the hide, and the bones of the ox in the inside fat, and then asked Zeus to make his choice. Zeus, though aware of the deception, chose the bones and the fat, "designing evil in his mind against mortal man," and in revenge withheld fire from man. Prometheus however secretly stole fire from heaven and gave it to man, and Zeus in return bound Prometheus with chains to a pillar, and sent an eagle to prey upon his liver. Zeus also, in order to injure man, created Pandora, and, after bestowing upon her numerous gifts, sent her to man a "beautiful mischief, for from her is sprung the race of women, of whom the race is thoroughly destructive." Hesiod, in his poem entitled 'Works and Days,' gives at greater length the legend of Pandora, and says that Zeus sent her to Epimetheus; and that he, not following the advice of Prometheus, who had told him never to receive a gift from Zeus, but to send it back again, took her into his house. These stories are supposed to have a meaning: Prometheus is the personification of *fore-thought*, and Epimetheus of *after-thought*.

There is another form of the legend respecting Prometheus, in which he is represented not merely as the friend and protector of the human race, but as their creator. This form is an old one, though neither Hesiod nor Æschylus has followed it. There is a fragment of Callimachus, in which he says, "If Prometheus formed thee, and thou art not sprung from some other clay." Plato has adopted this form of the legend in the 'Protagoras,' but with the variation that Prometheus is not the creator, but only the person who endowed man with his senses. He says that the gods formed all mortal animals within the earth, out of the mixture of earth and fire, and of as many things as are mingled with earth and fire, and that they entrusted to Prometheus and Epimetheus the business of providing them with all the faculties necessary for their preservation. He then proceeds to say that Epimetheus begged of Prometheus that he might have the business himself in the first place, and that Prometheus should overlook his work when he had done it. Epimetheus accordingly proceeds to his work, and bestows upon the different animals the means of preserving themselves; but when man came to be provided for, who was to be superior to all other animals, Epimetheus had been so prodigal of all his resources, that he had nothing left to bestow upon man. Prometheus, being at a loss how to remedy the omission of Epimetheus, steals from Hephæstus and Athena fire and the intelligence which is displayed in works of art, and gave them to man; so that by means of this wisdom, and fire as its instrument, men were endowed with the power of providing for themselves.

Some modern writers suppose that, in the earliest form of the legend, Prometheus was not considered as a deity, but simply as the representative of the human race, and that afterwards he was made a god, the friend and protector of man, and at last their creator.

Representations of Prometheus are frequent in the latter ages of ancient art, especially in allegorical representations of human life on sarcophagi, and in connection with the Fates, Eros and Psyche, and other legends. (Müller, 'Archäologie der Kunst,' § 396.)

PROMISSORY NOTE. [Bill of Exchange.]

PROMULGATION. Promulgation is from the Latin Promulgo, which is equivalent to Provulgo, and means "to make public." Blackstone observes of the promulgation of a law, "It may be notified by universal tradition and long practice, which supposes a previous publication, and is the case of the common law of England. It may be notified *vivâ voce* by officers appointed for that purpose, as is done with regard to proclamations, and such acts of parliament as are appointed to be publicly read in churches and other assemblies. It may lastly be notified by writing, printing, or the like, which is the general course taken with all our acts of parliament." A law being a command from a political superior to a political inferior to do or not to do something, with a penalty attached to the violation of the command, it is assumed that the command is made known in some way to all who are bound to obey it; or that it is known to all. But as to "a universal tradition and long usage," it is a mistake to say that it supposes a previous publication. A long usage does not of itself make law: the usage must be pronounced to be law by some competent authority, and that is the only promulgation which it has. Promulgation by proclamation only reaches those who hear it, and everybody cannot hear an act of parliament which is read in churches, for the churches would not hold one-fourth of the people if they all went to hear it read; and if they heard it read, very few would understand it. Printing is at present the most efficient means of promulgating a new statute; but to all those who cannot read it it is ineffectual; and so it is indeed to those who cannot understand it, which sometimes the judges themselves say they cannot do.

No remedy can be provided for these difficulties, and it is simply a positive rule of law that a new statute is binding on all persons who are under the authority of the power which makes the statute, from the moment that the statute is made and completed in due form. A person is presumed to know the law, because if he were allowed to urge ignorance of it as an excuse, it might be urged in so many cases as to give unbounded room for fraud. The positive rule that all the members of a state are bound by its laws, causes less evil than the admission of the excuse would.

Promulgation of a law among the Romans meant the placing of the bill (rogatio) in some public place where it could be read before it was voted upon in the Comitia. The Roman rule, which we also adopt, was that ignorance of law (ignorantia juris) was no excuse. (Paulus, *Dig.* 22, tit. 6. s. 9.)

PRONOUNS, the name given by grammarians to certain words which are used as substitutes for the names of persons and things. Pronouns properly so called are commonly divided into personal, demonstrative, relative, and interrogative pronouns; but it appears probable that all pronouns, at least with the exception of the first and second personal pronouns, were originally demonstrative. William Humboldt remarks that the first and second personal pronouns "are not mere substitutes for the names of the persons for whom they stand, but involve the personality of the speaker and of the person spoken to, and the relation between them;" and in writing and conversation there is frequently hardly any name which can so clearly designate the person intended as the appropriate personal pronoun. The third personal pronoun in English appears to have been originally a demonstrative, and to contain the same root, *ta*, *sa*, or *ha*, which occurs in the demonstrative pronoun in the Latin, Greek, and other cognate languages.

The relative pronoun may also be regarded as a demonstrative; for whether the pronoun is used to denote an object pointed out at the time by the speaker, or an object mentioned just before, or one which is to be immediately brought before the hearer's mind, it is equally demonstrative. In the last of these cases the pronoun is called a relative, as "I saw the man *whom* you mentioned." In English we have two forms for the relative, *that* and *who* or *which*. The former is the same word as the demonstrative; the latter contains the same root as we find in the Latin *qui*, the Sanscrit, Zend, and Lithuanian *ka*, and the Gothic *hver* and *kva*. The interrogative pronoun is the same as the relative in English and many of the cognate languages, and only differs from the relative in referring to something subsequent and unknown; whereas the latter refers to an antecedent and definite subject.

PRONUNCIATION. [Oratory.]

PROOF. [Demonstration; Evidence; Miracle; Oath; Probability.]

PROOF SPIRIT. A mixture of equal parts of water and alcohol is generally so termed, but legally proof spirit is defined by act of parliament to be "such as shall, at the temperature of 51° Fahr., weigh exactly $\frac{12}{13}$ths of an equal measure of distilled water." Such a mixture consists by weight of 50·76 water, and 49·24 alcohol; and its specific gravity is ·920. [Alcohol.]

PROPELLER. In works upon the construction of machinery the word *propeller* is used to indicate the arrangement by means of which motion is given to a carriage bearing a portion of the working gear required to traverse regularly in a horizontal direction; or to indicate a peculiar mechanism, set in motion by some mechanical power in vessels or ships which causes the latter to advance by the resistance offered by the water. The former class of propellers are most frequently employed in tools, and metal-working machinery, and consist of a fixed shaft bearing a screw thread, gearing into a nut working upon guides, so as only to be able to move laterally. The latter are more numerous, and may be said to consist of oars, sails, paddle-wheels, and screw-propellers. Sometimes the locomotive engine is used to propel loads on land; but this is so manifestly a modification of its tractive powers that it may for the present at least be neglected. Attention will in the following article be principally called to the propellers used for steam navigation, unquestionably the most important machines of this description now in use.

Until the application of the steam engine to the purposes of navigation, oars and sails were the only propellers used. Oars are, in fact, levers worked by hand against a fulcrum fixed on the boat itself, and causing the latter to advance by the reaction of the water upon the boat. Sails are propellers by reason of the resistance they offer to the movement of the wind, which thus exercises a motive power upon the vessel by its transmission to the hull, through the masts. Accordingly, therefore, as the sails are fixed with regard to the longitudinal axis of the ship, do they cause it to advance either in the line of the keel, to drop to leeward, or to turn on its vertical axis, with a velocity depending upon the size of the sails, the velocity of the movement of the wind, and upon the shape of the vessel. These various conditions come more especially under the province of ship-building, or of navigation, and are therefore only alluded to here incidentally.

The use of wheels bearing floats working in the water by the side of the boats to which they were fixed, had been known from a very remote period; but it was not until the steam engine was applied as a motive power to them that they were commonly introduced as propellers. At the present day the majority of steam-boats designed to work in comparatively still water, and even the majority of the vessels used in the deep-sea packet service, are provided with these organs of locomotion. It is found, indeed, that paddle-wheel steamers can attain a greater economical velocity than screw steamers hitherto have done; and the noise and vibration of the screw renders the class of vessel to which it is applied so uncomfortable, that it cannot be considered applicable to passenger traffic. Upon some rivers and large artificial canals, the waves caused by paddle-wheels are thought to be so injurious to the banks, that screw-propellers are substituted for them; but the agitation of the water below the surface produced by the revolution of the screw seems to be nearly as mischievous as the surface waves caused by the paddles; so that the most important advantage possessed by the screw propeller over the paddle-wheel, for narrow water-courses, finally resolves itself into the smaller width it allows to be given to the vessel. In deep-sea-going vessels, which do not carry passengers, the advantages of the screw are so great that nearly all the new traffic steamers are fitted with propellers of that description; and the company founded by Mr. Smith, in 1836, which built the Archimedes, has indeed already changed the whole condition of our commercial marine.

When paddle-wheels are used as propellers, they are placed upon a horizontal shaft or axis, and in front of the centre of gravity of the vessel; but there does not yet seem to be any uniformity of practice amongst constructors with regard to the precise position of those parts of the machinery; and even in the case of some of the canal boats used in Belgium the wheels are fixed at the stern, without any apparently disadvantageous results. In sea-going boats the wheels are, however, always placed on the outside, and about the middle of the boat; they are keyed upon a horizontal shaft bearing upon the solid framework of the ship's side, and almost always upon an external seating, carried by the framework of the paddle-box. The paddle-wheel shaft is continuous through the vessel when only one engine is used, and it is made in two pieces, with a movable clutch or coupling joint, when two engines are required, as is the case in all sea-going vessels. Motion is communicated to the shafts, either by means of cranks connected with the ends of balance beams, or with the piston heads of direct acting, or of oscillating, engines; and the position of the cranks towards one another is made such that the piston of one engine shall be able to exercise its full power, when the other is over its dead points. The wheels themselves consist of a series of radial arms, connected with one another by means of concentric rings (both the arms and circles being made of wrought iron), and upon the arms are fastened the floats, or the boards, whose revolution in the water produces the propulsive action. Very warm discussions have taken place with respect to the loss of power which necessarily attends the ordinary form of wheel, in which the floats are fixed radially to the wheel; and many ingenious contrivances have been proposed for the purpose of causing the floats to enter and to leave the water in a perpendicular direction. For vessels making short runs, the feathering paddles appear to produce satisfactory results; but it seems to be more than questionable whether the complication of the machinery, the additional weight of the wheels, and the consequent increase of power required to move them, do not more than compensate for the theoretical advantage gained by diminishing the slip observable in ordinary paddles. It is to be observed also, that numerous modifications of the form of the float boards have been introduced in order to diminish their inconveniences; and Field's wheel, in which the boards are divided into narrow slips, arranged in cycloidal curves, so as to enter the water at the same place in immediate succession, seems to be the best of its kind. Morgan's feathering wheel is one of the most successful of those engines; but after all the effective gain is very small, even with it. Generally speaking, the proportion of the useful effect of paddle-wheel engines to the power exerted is considered to be as 0·6 to 1·0 in the case of radial paddles; in the case of the feathering paddles it hardly exceeds 0·66 to 1·00, although at times it may rise to 0·833 to 1·000.

Whatever description of wheel be used, there is a point on its radii which describes a circle, known as the *rolling circle*, equal in its developed length to the distance actually traversed by the vessel during one stroke of the piston, and which serves to measure the ratio of the useful effect to the power exercised. It is important that the floats should be placed beyond this line, and in sea-going vessels exposed to cross, or rolling seas, the inner edge of the floats should even be kept at some considerable distance beyond it. There is still a remarkable discrepancy in the proportions assigned by different constructors to the various details of paddle-wheels, but the most generally received ones seem to be as follows. The diameter of the wheels is made equal to about from 4 to 4½ times the length of the stroke, in ordinary condensing engines of vessels designed for deep-sea sailing; the breadth of the wheel is made from $\frac{1}{3}$ to $\frac{1}{2}$ of the diameter; the width of the floats is made about $\frac{1}{10}$ of the diameter of the wheel; and their distance apart is made about 3 feet to 3 feet 6 inches. Some constructors make the surface of their floats dependent upon the area of the midship section; and its proportion then varies between $\frac{1}{10}$ and $\frac{1}{12}$ of the latter, the best proportion seeming to be about $\frac{1}{11}$ of the said section. The best velocity to be given to the outer edges of the floats appears to be $\frac{2}{3}$ of that of the horizontal velocity of the vessel. Wheels of large diameter may be used on rivers without inconvenience; but in sea-going vessels a practical limit is placed to the increase of this dimension by the effect of the rolling of the ship, and the wheels are rarely made more than $\frac{1}{2}$ greater in diameter than the depth of the hold; but it must be repeated that at present all these rules are little better than empirical ones.

The screw has been occasionally used as a propeller for many years, but it was not until 1836, as above stated, that its use became sufficiently understood to allow of its being applied commercially. In that year Mr. Smith attracted attention seriously to the subject; but Captain Ericsson may fairly be considered to be entitled to the merit of having been the first to overcome the practical difficulties connected with the application of this description of propeller. At the present day it certainly seems that for all ordinary deep sea goods traffic, and, the experience of the Dutch also shows, for steam transport on canals and narrow rivers, this description of mechanism will ultimately supersede every other one used for the same purpose. For vessels of war the sheltered position of the screw, and of the engines, give that description of propeller an incomparable advantage over the exposed engines and wheels of paddle-boats.

The screw-propeller ordinarily used may be described as consisting of two or more arms (though at the present day it is very rarely that more than three arms are used), forming parts of screws of large diameter arranged upon a central shaft. This shaft is set in motion, either by means of gearing, or by direct-acting engines working upon the crank of the shaft; so that the screw, being set in revolution, advances in the water in the same manner that a wood screw would advance in that material. The width of the screw is usually made equal to about $\frac{1}{6}$ of the convolution of the thread in small screws, and to nearly $\frac{1}{8}$ of that dimension in larger ones, whilst the pitch is found to be of the most advantageous proportion when it bears to the diameter the ratios of 1·2 to 1 in large screws, and of 1·4 to 1 in small ones. All these dimensions, however, must vary with the peculiar form of the ship, and its resistance to motion in the water; and in Bourne's 'Catechism of the Steam Engine,' or, better still, in his 'Treatise on the Screw-Propeller,' the several conditions affecting the proportions of the screw are carefully discussed. The screw is usually placed in the dead wood of the ship, immediately before the rudder; and its efficiency materially depends on the depth of its immersion; as also upon the fineness of the stern of the vessel, perhaps almost as much as upon the entry, or upon the midship section. The velocity of revolution of the screw seems to range between 50 and 70 revolutions per minute, according to the shape of the vessel and to the dimensions of the screw itself. The size of the vessel to which the screw-propeller is applied seems to have a more favourable influence upon the useful effect produced, than is the case when the paddle-wheel is used; and for this reason also it is preferred for vessels of heavy burden and deep immersion.

In a well proportioned vessel, provided with a screw-propeller of the best form and mechanical conditions, there is very little slip or loss of the velocity attained by the screw itself; and it may be considered to range between 10 and 30 per cent. There is, however, a greater loss of the power developed by the engine in screw steamers than in paddle boats, in consequence of the friction and of the passive resistances to be overcome. This fact renders the use of the screw-propeller inadvisable on board vessels which trust mainly to their steam power; because it renders necessary the transport of a larger quantity of coal. Under ordinary circumstances it seems, however, that in cases where the paddle-wheels are kept at their normal immersion, and they are so proportioned as not to give an unnecessary amount of slip, they possess a slight mechanical advantage over the screw, for the purposes of propulsion. When the vessel is brought too deep in the water, or when the action of the sea disturbs the working conditions of the wheels, or when a side wind depresses one wheel whilst it leaves the other with an insufficient immersion, the advantage is in favour of the screw-propeller. Perhaps the screw interferes more with the steering properties of a ship than the paddle-wheels do; because when it ceases to be in motion its blades form a species of fan which intercepts the stream of water which would otherwise strike the rudder. The greater facility with which the screw-propeller can be adapted to the combination of steam and sail power more than compensates for this occasional inconvenience, which after all ceases to be felt when the ship is in the hands of an able seaman. The screw is least advantageous against head winds.

The majority of the screws used in the merchant service are made of cast iron, and they are cast solid. In the Royal Navy they are often made of brass; and on some occasions they are even forged of wrought iron. A very great number of modifications of their forms has been proposed, both for the purpose of obviating the loss of power occasioned by the slip, and of preventing the interference with the action of the rudder. Feathering screws, movable screws, converging blades, screws with a pitch increasing at their extremities, corrugated screws, Griflith's screw, with a circular boss upon the shaft, Beattie's screw, placed behind the rudder, lifting screws, and other contrivances, literally too numerous to mention, testify at least to the earnest character of the efforts made to remedy the inconveniences, real or imaginary, of a mechanical agent of such importance. Hitherto the results attained by these modifications have been far from satisfactory, and for ordinary traffic at least the screw is made upon nearly the same principles as it was in the earlier essays. It may perhaps be fair here to state that much of the merit of overcoming the difficulties attending the application of the screw-propeller was due to the late Mr. Brunel, on the occasion of the construction of the Great Britain; and he, in conjunction with Mr. Scott Russell, subsequently tried an experiment on a larger scale, in the application of both paddle and screw propulsion in the Great Eastern—with what commercial success remains yet to be seen.

(The best treatises in English upon the subject of steam propulsion in its different forms are Tredgold on the *Steam-Engine* and its Supplements; Hann and Genner on the *Steam-Engine*; Bourne, on the *Screw-Propeller*, and his *Treatise on the Steam-Engine*.)

PROPERTY is derived, probably through the French language, from the Latin word *Proprietas*, which is used by Gaius (ii. 89) as equivalent to ownership (*dominium*), and is opposed to *possessio*. [POSSESSION.] The etymology of the word *proprietas* (*proprius*) suggests the notion of a thing being a man's own, which general notion is contained in every definition of property. Blackstone (ii. 1) defines "the right of property" to be "that sole and despotic dominion which one man claims and exercises over the external things of the world, in total exclusion of the right of any other individual in the universe." A foreign writer defines ownership or property to be "the right to deal with a corporeal thing according to a man's pleasure, and to the exclusion of all other persons."

This definition excludes incorporeal things, which however are considered objects of property in our law, and were also considered as objects of property in the Roman law, under the general name of *jura*, or *jura in re*; they were considered as detached parts of ownership, and so opposed to *dominium*, a word which represented the totality of the rights of ownership. (Savigny, 'Das Recht des Besitzes,' 5th ed., p. 166.) This definition also describes property as consisting in a right, by which word right is meant "a *legal* power to operate on a thing, by which it is essentially distinguished from the mere possession of the thing, or the physical power to operate upon it. Consequently such a right is not established by the possession of the thing; and it is not lost, when the possession of the thing is lost. Such a right can also be enforced by him who possesses the right by an *actio in rem* against every person who possesses the thing, or disputes his right to it." (Mackeldey, 'Lehrbuch des heutigen Röm. Rechts,' ii., pp. 1 36.) This definition, which is characterised by a precision and accuracy which are altogether wanting in that of Blackstone, is here adopted. By property, then, is here understood only that which the positive law of a country recognises as property, and for the protection or recovery of which it gives a remedy by legal forms against every person who invades the property, or has the possession of it.

Austin observes ('An Outline of a Course of Lectures on General Jurisprudence') that "dominion, property, or ownership is a name liable to objection. For, first, it may import that the right in question is a right of unmeasured duration, as well as indicate the indefinite extent of the purposes to which the entitled person may turn the subject. Secondly, it often signifies property, with the meaning wherein property is distinguished from the right of possession. [POSSESSION.] Thirdly, dominion, as taken with one of its significations, is exactly co-extensive with *jus in rem*, and applies to every right that is not *jus in personam*." The first sense of the word property is expounded by determining, as hereafter explained, the quantity and quality of an estate as understood in English law. As to the second, possession is of itself no right, but a bare fact, and its relation to rights *in rem* is the same as the physical to the legal power to operate on a thing. The doctrine of possession is therefore distinct from and should precede the doctrine of property. [POSSESSION.] The third sense of property has reference to the legal modes of obtaining the possession of a thing in which a man can prove that he has property and a present right to possess.

A complete view of property, as recognised by any given system of law, would embrace the following heads, which it would be necessary to exhaust, in order that the view should be complete. It would embrace an enumeration of all the kinds or classes of things which are objects of property: the exposition of the greatest amount of power over such things as are objects of property, which a man can legally exercise—and connected with this, the different parts or portions into which the totality of the right of property may be divided, or conceived to be divided: the modes in which property is legally transferred from one person to another—that is, acquired and lost: the capacity of particular classes of persons to acquire and transfer property as above understood; or, to take the other view of this division, an enumeration of persons who labour under legal incapacities as to the acquisition and loss of property.

The following general outline of property is adapted to the English system of Law; it may be filled up by references to other articles in this work, or to treatises:—

1. The kinds or classes of things which are objects of property.

The general division is into Things Real and Things Personal, the incidents to which are so different in the system of English law that they must be separately considered.

Things Real are comprehended under the terms of Lands, Tenements, and Hereditaments. The word hereditaments is the most comprehensive of these terms, because it comprehends every thing which may be an object of inheritance, both things real and also some personal things, such as heirlooms, which are objects of inheritance.

Hereditaments are divided into Things Corporeal and Incorporeal. A Corporeal Hereditament is land, in the legal sense of the term. An Incorporeal Hereditament is defined by Blackstone to be "a right issuing out of a thing corporate (corporeal), whether real or personal, or concerning or annexed to, or exercisable within the same." Perhaps the definition is not quite exact, and it would not be easy to make an exact definition. The Things Incorporeal of the English law correspond in their general character to the *res incorporales* of the Roman law, one distinguishing character of which is that they are incapable of tradition or delivery (Gaius, ii. 28): the *res corporales* of the Roman law are things which are capable of tradition, whether moveable, as a horse, or immoveable, as a house. The incorporeal hereditaments enumerated by Blackstone are, advowsons, tithes, commons, ways, offices, dignities, franchises, corodies or pensions, annuities, and rents.

2. The greatest amount of power over such things as are objects of property which a man can legally exercise.

To this head belongs the English doctrine of Tenure, or the various ways in which land is said to be *held*. Though this was a much more important part of English law than it now is, it is still of importance; for tenure always exists wherever there is the relation of landlord and tenant. As all land in the kingdom is held mediately or immediately of the crown, it follows that a man cannot have a property in land which shall not be subject to this right of the crown. He cannot operate upon his property in land in any way so as to destroy this right; and consequently the utmost amount of property in land which a man can have is limited. The interest which a man can have in any land, tenement, or hereditament, is called an Estate; and this word comprises the greatest amount of power and enjoyment, both as to time and manner, which a man can legally have over and in any of the three things just enumerated, as well as the smallest legal amount of such power and enjoyment: it also comprises, under the notion of time, the determination of the period when his power and enjoyment shall commence, as well as when they shall cease. Lands, tenements, and hereditaments then being objects of property, a man may either have the most complete property in such things which is legally allowed, or he may have the least property in them which the law allows; and both this complete and this limited property is expressed by the word estate. An estate in a thing is property in a thing, and property in a thing is legally considered to be capable of division into defineable parts, called estates, each of which estates has its defineable legal incidents. With reference to an estate, the time during which the right of enjoyment continues is usually expressed by the term quantity of estate. The manner in which the enjoyment is to be exercised during this time is often expressed by the term quality of estate:

thus a man may enjoy an estate solely or in joint-tenancy; his enjoyment may be co-extensive with the largest amount of legal enjoyment of any estate, or it may be limited by the contemporaneous rights of others in or to the property in which he has an estate; that is, he may have the legal enjoyment for a determinate time, subject to various limitations and abridgments of the fullest enjoyment of property. The time when the enjoyment of the estate shall commence is also considered a part of its quality; and the time of enjoyment commencing is either present—that is, contemporaneous with the acquisition of the estate—or future. It may not be useless to remark, that here and elsewhere, where the word estate is used in its technical sense, it does not mean the thing enjoyed, but the quantity and quality of enjoyment of the thing.

Independent of the quality and quantity of an estate, there is another modification of property which requires notice. A person may have the estate both as to quantity and quality in the sense above explained, either with or without the right to the beneficial enjoyment. The person who has merely the estate in quantity and quality, has the bare legal estate. He who has not the right to the estate in quantity and quality, as above explained, but merely to the enjoyment of such estate, while the other has not, is said to have the equitable estate. The term quality of estate might be used to express this equitable interest; but inasmuch as we want a word to express the manner and mode of enjoying an estate as distinct from the time of enjoyment, and as quality is the word used to express that manner and mode, it must not be used in a different sense. The explanation of the nature of an equitable as distinguished from a legal estate belongs to Uses and Trusts.

It has been said that this distinction between legal and beneficial or equitable property is peculiar to the English law. (Lord Mansfield, 1 'T. R.,' 759, n.) But these two kinds of property existed in the Roman law, and the theory of the division of ownership or property into *quiritarian*, or legal, and *bonitarian*, beneficial, or equitable, was fully developed. Its origin in the Roman law is not certain; but it is a probable conjecture that its origin so far resembled the origin of the like division in English law, that it was due to the attempt to get rid of the difficulties attending the alienation of property by the old legal forms. "There is," says Gaius (ii. 40), "among other nations (*peregrini*) only one kind of ownership or property (*dominium*), so that a man is either owner or not; and it was the same in the old Roman law, for a man was either owner *ex jure quiritium*, or he was not. But ownership was afterwards divided, so that one man may now be owner of a thing *ex jure quiritium*, and another may have the same thing *in bonis*. For if, in the case of a *res mancipi*, I do not transfer it to you by *mancipatio*, or *in jure cessio*, but only deliver it, the thing indeed will become yours beneficially (*in bonis*), but it will remain mine legally (*ex jure quiritium*), till you have acquired the property by usucapion; for as soon as the time of usucapion is completed, from that time it begins to be yours in full ownership (*pleno jure*); that is, the thing begins to be yours both *in bonis* and *in jure*, just as if it had been transferred by *mancipatio* or in *jure cessio*." This passage seems to suggest a conjecture as to the origin of the distinction between legal and equitable property which was of so much importance in Roman law. The distinction between the two kinds of ownership or property was as clearly marked as in our system, though it was not applied to all the purposes to which this divided or double ownership is applied in our system.

3. The modes in which property is legally transferred from one person to another.

Property may either be acquired in a single thing, or in several things of the same kind at one time; or it may be acquired in a great variety of different kinds of things at the same time, which pass to the new owner, not as individual things, but as the component parts of a whole property. The Roman law designated the former mode of acquisition by the term *acquisitio rerum singularum*; and the latter by the term *acquisitio per universitatem*. Though the two modes of acquisition exist in our law, there are no names for them by which they are placed in opposition to one another. The case of *acquisitio per universitatem*, or of universal succession, occurs when a man is made a bankrupt or insolvent, and an assignee or assignees are appointed [BANKRUPT; INSOLVENT], in which cases the whole of a man's property, real and personal, as well as his rights and obligations generally, become the legal property of the assignee or assignees, and is applicable and must be applied according to the rules of law in the cases of bankruptcy and insolvency. With respect to personal property, universal succession occurs when a man by his last will appoints an executor; and an administrator with the will annexed, or without the will annexed when there is none, thereby acquires the whole personal property of the intestate. Both the heir and devisee also, in a sense take by universal succession.

As to both singular and universal succession, the modes of acquisition of estates in things real are reducible to two general heads—descent and purchase. "Descent, or hereditary succession, is the title whereby a man on the death of his ancestor acquires his estate by right of representation as his heir at law" (Blackstone); and an estate so acquired is commonly called an estate of inheritance.

Purchase, which is corrupted from the Latin word *perquisitio*, is defined by Littleton (i. 12) to be "the possession of lands or tenements that a man hath by his deed or agreement, unto which possession he cometh not by title of descent from any of his ancestors, or of his cousins (*consanguinei*), but by his own deed." Purchase, as thus defined, comprehends all the modes of acquiring property by deed or agreement, and not by descent; but it is not a complete description of purchase, as now understood, for it omits the mode of acquisition by will or testament, which, however, when Littleton wrote, was of comparatively small importance, as the power of devising lands did not then exist, except by the custom of particular places. Blackstone makes the following enumeration of the modes of purchase: Escheat, Occupancy, Forfeiture, and Alienation. As to escheat, there is some difficulty in the classification, as the title appears to be partly by descent and partly by purchase.

The head of alienation comprehends every form by which a man transfers property to another: it comprehends, therefore, both alienations made by a person during his life, and the disposition of his property by his last will and testament. The disposition of property by will has this peculiarity about it, that though the instrument must be completed in legal form during the lifetime of the giver, the persons to whom the property is given do not thereby obtain the property; they only obtain it by the death of the giver, who by that event becomes incapable of giving, but whose continuing intention to give is testified by the continuing existence of the instrument of gift.

The particular modes of alienation by deed are to a certain extent determined by the estate which the alienor possesses, and the estate or estates which he intends to transfer. The forms of alienation are noticed under their various heads.

4. The legal capacity for the acquisition of estates in lands, tenements, and hereditaments, is most briefly and conveniently shown by the enumeration of the classes of persons who labour under legal incapacity; and in like manner, as to the alienation or loss of estates, it is most conveniently shown by enumerating the persons who, owing to mental incapacity, infancy, or other causes, labour under legal incapacity to transfer or lose estates. This division comprehends so much of the status of aliens, infants, lunatics, and married women, as relates to the acquisition or loss of estates.

Personal property is not sufficiently described by the term "moveables," for certain estates in land are personal property, and are comprehended under the term chattels real. Terms for years are an example of chattels real; and they pass together with the rest of a man's personal estate to the executor, the universal successor. Chattels personal are all other personal property, and are said by Blackstone "to be properly and strictly speaking things *moveable*, which may be annexed to or attendant on the person of the owner, and carried about with him from one part of the world to another. Such are animals, household stuff, money, jewels, coin, garments, and everything else that can properly be put in motion, and transferred from place to place." Personal property as thus defined corresponds to the *mobilia* or *res mobiles* of the Roman law; but this is a very inadequate description of personal property as recognised by the English law. And herein we first perceive the greater certainty and distinctness of the law relating to real property compared with the law relating to chattels; the things which can be the objects of real property are defineable, as well as the estates that can be had in them; the things that can be the objects of personal property are hardly determinable, and the estates, or more properly the interests, which a man may have in them, are perhaps also less determinate. As examples of objects of personal property, which in no way come within Blackstone's description, we may instance patent-rights, which are things incorporeal, though not hereditaments, and are the objects of property.

A quantity of stock in the public funds is not money, though often talked of as such, but still it is property. Even debts due to a testator or intestate are considered as property with respect to probate and letters of administration; still they are not expressed by the term goods and chattels in the letters of administration, but by the term "credits," for as debts are not the property of a man to whom they are due, so they cannot become property because he happens to die. Things can be assigned by the person who has a claim to them, though they may be things which cannot be called his property: a chose in action is an instance of this. Blackstone observes: "the money due on a bond is a chose in action: for a property in the debt vests at the time of forfeiture mentioned in the obligation, but there is no possession till recovered by course of law." He had just before spoken of the nature of property in action being such that a man "hath not the occupation, but merely a bare right to occupy the thing in question.' From this it appears that he treats a debt due to a man as a property belonging to him, whereas the debt due merely gives a right of action to recover a determinate sum of money, or a sum which is less than some determinate sum. In this instance, says Blackstone, "the property or right of action depends upon an express contract or obligation to pay a stated sum." Here he uses property and right of action as synonymous, which is incorrect; for property implies a determinate thing, and a right of action may be either for a determinate thing or to compel a person to do some determinate act. The thing claimed is properly enough called a "thing in action," but the action is not to have a thing, but that the defendant shall do a certain act. Blackstone observes, in a note, that the same idea and the same denomination of property prevailed in the civil law, but this is a mistake. In the first passage ('Dig.' 41, tit. 1, s. 52), to which he refers in support of his statement, it is clear that a corporeal definite thing is spoken of, which the commentator could hardly have doubted about, if he had given in his note the whole of the passage instead of a part of it. The passage is this: "a thing is a man's *in bonis*, whenever he can defend his possession of it by a plea (*exceptio*), or recover it when lost by an *actio*." This *actio* would be in rem: the declaration of the plaintiff would affirm that the thing was his. In the other passage quoted by Blackstone ('Dig.' 50, tit. 16, s. 49), things which consist "in *actionibus, petitionibus, persecutionibus*" are included among the things *in bonis*; but the things in action so spoken of are things which a man has not, as contrasted with things which a man has, in his possession, and these are things corporeal, things determinate. Besides, even if we should admit that the Roman law treated a debt as a thing *in bonis*, it did not treat it as property, for a thing *in bonis* was not property in the sense in which Blackstone is here using property. Further, when a Roman claimed a debt, his declaration was that something ought to be given to him or done for his benefit by the defendant; and this "giving" always meant giving something which did *not* belong to the plaintiff, for it was a principle of Roman law that you could not give to a man what already belonged to him. But the Roman law had a precision in these matters of which the commentator had not the slightest idea.

From these remarks it will appear, first, that there is a difficulty in classifying the things that are objects of personal property; second, that things, as choses in action, are not property, and yet they can be transferred (in equity) as if they were property. Accordingly it happens that it is sometimes difficult to say whether a particular thing is an assignable thing or not, whether in its nature it is capable of any transfer.

Property in chattels may, like property in things real, vary as to quantity and quality of interest, though things personal are not capable of such extended and various modifications, analogous to estates, as things real are. As to quantity, that is, duration, a man may have the use of a personal thing for life, and another may have the absolute property in it after his death. As to quality, persons may own a thing personal as joint tenants and as tenants in common. There is an equitable property in chattels as well as in things real. Money, for instance, is often paid to a trustee, in order that he may give the interest of it to one person for life, and after his death pay the money to another. The trustee, so long as he holds the money, has the legal property in the money, and in the thing in which the money is invested. A legatee has only an equitable interest, even in a specific legacy, after his testator's will is proved, until the executor gives the thing to him, or in some clear way admits his right to it.

The modes of acquiring and losing personal property are reduced by Blackstone to the following principal modes:—Occupancy; prerogative, whereby a right accrues to the crown or the crown's grantee; forfeiture, which is a punishment for a crime or misdemeanour; custom, as heriots, &c.; succession, by which term Blackstone understands the capacity of a corporation aggregate to take what their predecessors had; marriage, by which the husband acquires the chattels of the wife, and the right of suing for her choses in action, and a peculiar kind of interest in her chattels real; judgment; gift or grant; contract; bankruptcy and insolvency, so far as relates to chattels; testament; administration. The enumeration taken from Blackstone is not here offered as one that is complete or altogether unexceptionable. Under contract Blackstone includes sale, as to which it may be observed that the formalities required by the law for the transfer of ownership in things personal are few; but the difficult questions which arise as to the transfer of property in personal things are probably much more numerous than in the case of estates in things real.

Under contract he also comprehends bailment, by which "a special qualified property is transferred from the bailor to the bailee together with the possession." This qualified property, as it is called, gives the bailee a right of action against all persons who injure or take away the chattels; and Blackstone, as usual, finds a reason for this right of action. This right of action is however really founded on the right of possession, and it is just the same right of action that a man has who finds a thing, against any person, except the owner, who injures or takes away the thing. This right, when understood, is in all respects consistent with sound principles; and there is no objection to calling it a right founded on a qualified property, when the term qualified property is rightly understood. Under contract, he also includes hiring and borrowing, and these also are contracts which, he says, may transfer a qualified property to the hirer or borrower. The same remarks apply to this kind of property as to that acquired by bailment. There is, however, a case in which a man must acquire an absolute property by borrowing, as in the case of the Roman mutuum, when the thing borrowed is a thing which consists "*pondere, numero*, or *mensurâ*," as, for instance, so many pounds of butter. The distinctions of the Roman law between hiring, "*locatio et conductio*," lending, "*mutuum*," "*commodatum*," and "*depositum*," are founded on unchangeable principles, and are expounded in that system with a clearness which, in this respect, ours perhaps does not admit.

The incapacities of persons as to acquiring personal property are fewer than those as to real property; and the incapacities to transfer and lose are also fewer. But a complete enumeration of the classes of persons who labour under either of these incapacities, and the particular incapacities of each of such classes, would probably be more difficult than a like enumeration as to estates in real property.

PROPERTY-TAX. [Taxation.]

PROPHECY (*προφητεία*, a foretelling, or the power of foretelling) in its popular acceptation is a foretelling, or a thing foretold. In classical Greek, *prophétes* (*προφήτης*) corresponds with the Latin *vates*, which indeed may be regarded as the same word without the preposition. In the Old Testament, the Hebrew *nevuah* (to bubble forth) implies something of inspiration; but in Numbers xii. 6, there is a difference made between Moses, with whom God spake "mouth to mouth," and other prophets, with whom he spoke "in a dream." In Exodus vii. 1, Aaron is directed to be the "prophet" of Moses, or, as is explained in Exodus iv. 16, his interpreter, or to "be to him as a mouth." St. Paul uses *prophetes* (Tit. i. 12), which is rendered "prophet" in the authorised version, but "poet" by Tyndale; and probably Epimenides is meant. S. Chrysostom ('Hom. in 1 Cor.') says that *prophetes* is the same as *herméneutes* (ἑρμηνευτὴς), an interpreter; and Festus says that the chief priests of the temples and interpreters of the oracles were by the ancients called prophets.

Under Oracle it is observed that there were current in ancient Greece numerous so-called prophecies, but they were dark and ambiguous. This is not the case with the prophecies recorded in the Bible. Some of these were extant in books written long before the events took place to which they refer, such as the prophecy concerning Abraham's posterity, their extraordinary increase, their sufferings in Egypt four hundred years, their sojourning in the wilderness, and their possessing at length the land of Canaan. The numerous prophecies in the Old Testament pertaining to the Messiah, with their accomplishment recorded in the New Testament, and the prophecies of Jesus and his Apostles, are so familiar to the minds of all, that they need not be specified. The prophecies of the Old and New Testament, which have been long fulfilled, afford altogether an amount of evidence which, if really understood, it seems impossible to resist, in proof of the Bible being a revelation from God.

The prophecies of the Old and New Testament are understood by all believers in scriptural prophecy to be predictions of future events pronounced by persons who, on the occasion of delivering such predictions, were directed and governed by the Deity. The first thing to establish in the examination of these prophecies is the genuineness of the books in which they are contained. The question is, whether the prophecies in the form in which we have them, were delivered before the events to which it is alleged that they refer. This is purely a matter of historical criticism, and in no respect differs in the manner of carrying on the investigation, from an inquiry of a like kind as to any other book. The next inquiry is to compare the alleged prophecy with the events of which it is alleged that it was a prediction. This, though apparently the easier part of the inquiry, is one wherein much difference of opinion may exist. Some of the prophecies are clear and precise in their terms; and when the former part of the inquiry has had a satisfactory result, no unprejudiced person can doubt that the prophecies do refer to certain definite events. Some of the prophecies are in their terms vague and general; and others refer to events which, it is admitted, have not yet been accomplished. So far as it is admitted that any prophecy has not been accomplished, so far it must be admitted that prophecy fails in being substantiated by the only evidence that can establish its truth. It is then on those events which all believers allege to be events accomplished, in conformity to genuine predictions, that the proof of prophecy depends. The method of investigation is that which has been already mentioned, and every man should come to it with an unprejudiced mind.

PROPIONAMIDE. [Propionyl.]

PROPIONE. [Propionyl.]

PROPIONIC ACID. [Propionyl.]

PROPIONIC ALDEHYDE. [Propionyl.]

PROPIONITRYL. [Ethyl, *cyanide of*.]

PROPIONYL ($C_6H_5O_2$). The radical assumed to exist in a number of organic compounds collectively known as the propionic group, and of which the chief member is propionic acid. The name is derived from *πρῶτος*, *first*, and *πίων*, *fat*, because propionic acid is the first in the series of fatty acids, which separates as an oily layer when liberated in aqueous solutions of its salts.

Hydride of propionyl ($C_6H_5O_2$, H). *Metacetic* or *propionic aldehyde*.—This is one of the products of the oxidation of albumen, fibrin, or casein, by a mixture of sulphuric acid with either binoxide of manganese, or bichromate of potash. It is isolated from other matters that are obtained at the same time, by fractional distillation.

Hydride of propionyl is a limpid liquid, of agreeable ethereal odour, sp. gr. 0·79; boiling point between 130° and 150° Fahr., and vapour density 2·111. It slowly acidifies when exposed to the air.

Hydride of pentachloropropionyl ($C_6Cl_5O_2$, H), or *propionic chloral*, is one of the products of the action of hydrochloric acid and binoxide of manganese upon starch. It is an oily liquid, crystallising in rhombic tables on exposing to a temperature of 32° Fahr.

Propione ($C_{10}H_{10}O_2$), or the *ethylide of propionyl* ($C_6H_5O_2$, C_4H_5).—The product of the destructive distillation of propionate of baryta. It is a colourless or slightly yellow-coloured liquid of agreeable odour, insoluble in water, but soluble in alcohol or ether. Its boiling point is 212° Fahr. It is inflammable, burning with a pale blue flame. Nitric acid converts it into propionic acid.

Propionic anhydride, or anhydrous propionic acid $\left(\left.\begin{matrix}C_6H_5O_3\\C_6H_5O_3\end{matrix}\right\}\right)$ is a colourless liquid formed on distilling a mixture of two equivalents of oxychloride of phosphorus, and six of dried propionate of soda. It has a disagreeable odour, is not soluble in water, and boils at 329° Fahr.

Propionic acid $\left(\left.\begin{matrix}C_6H_5O_3\\HO\end{matrix}\right\}\right)$. ***Metacetic acid, or metacetonic acid.***—This acid is one of the products of the oxidation of oleic acid; it is also produced by the action of strong caustic potash upon sugar, starch, gum, or mannite, and by the action of ferments upon glycerin. The most convenient method of preparing it is to add cyanide of ethyl drop by drop to a concentrated alcoholic solution of potash contained in a retort. The reaction that then takes place is thus expressed:—

$$\underbrace{C_4H_5, C_2N}_{\text{Cyanide of ethyl.}} + \underbrace{2HO}_{\text{Water.}} + \underbrace{KO, HO}_{\text{Potash.}} = \underbrace{KO, C_6H_5O_3}_{\text{Propionate of potash.}} + \underbrace{NH_3}_{\text{Ammonia.}}$$

On distilling the residue with sulphuric acid, or with syrupy phosphoric acid, pure propionic acid passes over.

Propionic acid crystallises in plates. On the application of a gentle heat it fuses, and at 284° Fahr. boils. It is very sour, and has a pungent odour, somewhat like a mixture of butyric and acrylic acids. Water takes up a large quantity of it, excess floating like an oil upon the saturated solution.

Propionates, or the salts of propionic acid, are mostly crystalline, and soluble in water. They are all monometallic, and easily decomposed by strong acids. *Propionate of potash* is very deliquescent. *Propionate of soda* crystallises with difficulty; it forms a *double salt* with acetate of soda, crystallising in needles, and containing ($C_4H_3NaO_4$, $C_6H_5NaO_4 + 9$ Aq). *Propionate of baryta* ($C_6H_5BaO_4$) crystallises in prisms. *Propionate of lime* forms silky fibres. *Propionate of copper* ($C_6H_5CuO_4$ + Aq.) crystallises in small oblique prisms: it is very soluble in alcohol, but only slightly so in water. *Propionate of lead* is uncrystallisable. *Propionate of silver* ($C_6H_5AgO_4$) crystallises in tufts of needles; it forms a *double salt* with acetate of silver, containing ($C_4H_3AgO_4$, $C_6H_5AgO_4$). *Propionate of ethyl; propionic ether; metacetic ether* ($C_6H_5(C_4H_5)O_4$) is obtained on distilling propionate of soda with alcohol and sulphuric acid. It is lighter than water, boils at 213°·8 Fahr., and has an odour resembling rum.

Nitropropionic acid ($C_6H_5(NO_4)O_4$), *nitrometacetic acid*, is a heavy yellow oil slightly soluble in water, but very soluble in alcohol. It possesses an aromatic odour and a sweet taste, and is inflammable, burning with a reddish flame. It forms crystalline monometallic salts with bases. For the method of preparing it, see BUTYRIC ACID, *butyrone*.

Propionamide, or nitride of propionyl $\left(\left.\begin{matrix}C_6H_5O_2\\H\\H\end{matrix}\right\} N\right)$ results from the action of ammonia on propionate of ethyl.

PROPORTION. There must be in the mind of every person, antecedently to all mathematical instruction, a perfect conception of proportion, though not perhaps of the manner of measuring magnitudes with a view to express their proportions by means of numbers. All who can trace the resemblance of a drawing to the original, or have the least notion of the use of a map, are in possession of the fundamental notions on which a theory of proportion can be founded. The term RATIO is that under which the first part of the subject should be treated, and the article cited will contain matter preliminary to the present one. It will be sufficient for our present purpose to state that the ratio or relative magnitude of two magnitudes is to be measured by the number of times or parts of times which one is contained in the other, whenever the two are commensurable; and we shall now confine ourselves to the purely mathematical treatment of the theory of proportion, and shall avoid, as much as the nature of the subject will admit, all discussion of the notion of ratio considered as a magnitude.

We cannot well explain the nature of the difficulty which occurs in the theory of proportion, without a prior reference, first, to the purely arithmetical treatment of the subject, and secondly, to the *practical* sufficiency of this method which is the necessary consequence of our physical constitution.

If all magnitudes of the same kind were necessarily commensurable, that is, if any one among them being taken as a unit, the rest were all expressible by multiples, aliquot parts or submultiples, and multiples of aliquot parts, of the unit chosen, no difficulty would arise in making the subject of proportion purely arithmetical. For let a and b represent the units, parts of units, or both, in two magnitudes of the same kind (as two lines); any sufficient demonstration of the rule for the division of one fraction by another will show that a contains b precisely a number of times and parts of times. If then we say that a is to b in the same proportion as c to d, we mean that a contains b precisely such times and parts of times as c contains d: that is, we assert the equation

$$\frac{a}{b} = \frac{c}{d};$$

the mathematical treatment of which is so easy, that no one who can solve a simple equation can be stopped for a moment by the difficulty of any consequence of it. The following proposition, which may be proved generally, contains all the consequences which are most useful. Let a, b, c, and d be (in the arithmetical sense) proportional: take any two functions of a and b, which are homogeneous and of the same dimension (such as $ab + b^2$ and $a^2 - b^2$). Take corresponding functions of c and d (which are $cd + d^2$ and $c^2 - d^2$); then the four numbers so obtained are also proportional (that is, $ab + b^2$ contains $a^2 - b^2$ as many times and parts of times as $cd + d^2$ contains $c^2 - d^2$).

In measuring magnitudes of which the numerical representatives are afterwards to be submitted to calculation, it necessarily follows, from the imperfections of our senses, that some imperceptible amount of magnitude must always be neglected or added; so that, for example, that which we call a line of 3 inches long means something between 2·9 and 3·1, or 2·99 and 3·01, or 2·999 and 3·001, according to the degree of accuracy of the measurement. All magnitudes therefore are practically commensurable; for suppose, in the case of weights for example, that a grain is taken as the unit, and that the ten-thousandth part of a unit is considered as of no consequence; then by taking every weight only to the nearest ten-thousandth of a grain, they may every one be expressed arithmetically with a conventional degree of precision, which for every purpose of application will do as well as though it were perfectly accurate.

The discovery of INCOMMENSURABLE magnitudes, one of the most striking triumphs of reason over the imperfection of the senses, was made at a very early period; since the demonstration of their existence, the classification (to a certain extent) of their species [IRRATIONAL QUANTITIES], and the means of overcoming the difficulties which they present, appear in the writings of Euclid. A moment's consideration will show that a property of numbers, a relation of figure in geometry, a general law of nature, may be inferred from induction with a degree of probability which will amount to moral certainty, both as to the exactness and universality of the property, relation, or law. But the existence of incommensurable magnitudes can never be made certain, except by absolute deduction: no attempt at measurement, a *minimum visibile* existing, could show the non-existence of any common measure, however small. Suppose for instance that, having provided means of measurement which can always be depended on to show the *thousandth* of an inch, but nothing less, a person should accurately (as the word is commonly used) lay down squares of one, two, &c., inches in the side, with a view to render the existence of a common measure to the side and diagonal exceedingly improbable by experiment. If not before, he would be baffled by the square whose side is 2378 inches, the diagonal of which could not by his measures be distinguished from 3363 inches, from which it differs only by about the *five-thousandth* part of an inch. And let any greater degree of exactness be attained in the means of measurement, short of positive accuracy, a reasoner on the subject could still predict a square which should defeat the attainment of the object sought.

The mere existence of incommensurables, to say nothing of their frequent occurrence, and the impossibility of avoiding them, renders the arithmetical theory of proportion inexact in its very definition. If we would say, for instance, that the diagonal of a larger square is to its side as the diagonal of a smaller square is to its side, we enunciate a proposition the meaning of which is unsettled. For if we mean to assert that the larger diagonal contains the larger side as many times or fractions of times as the smaller diagonal contains the smaller, it is answered, by those who wish for precise notions, that neither diagonal contains its side any exact number of times or parts of times. If we should say that the larger diagonal lies between 1·414213 and 1·414214 times the larger side, and that the smaller diagonal also lies between 1·414213 and 1·414214 times the smaller side, and if we should show this to be true, we certainly show that we could produce lines very nearly equal to the diagonals, which are, under the arithmetical definition, proportional to the sides; and that this might be done without altering either diagonal by so much as the millionth part of the side. And the ten millionth, hundred-millionth, or any aliquot part of the side, however small, might be substituted for the millionth, without detriment to our power of showing the truth of the proposition. If we use the means by which this process may be carried on *ad infinitum*, we may perhaps be said to have established the truth of the proposition that the diagonals of squares are as their sides. But if we in any manner stop short of this, we destroy the rigorous character of geometry, and produce a system of mathematics which, like a common table of logarithms, is true to a certain number of places of decimals, and not farther. It is obvious that such a system of mathematics, like the table with which we have compared it, is sufficient for the purposes of practical application; nor have we the least quarrel with those who, desiring an instrument only, are content with one which is sharp enough for their purpose. We only complain of them when they assert and teach others that their tool has an edge keen enough to separate the minutest truth from the minutest falsehood; whereas, on examining it with a powerful microscope, we find the so-called sharp edge capable of being magnified into a plane of any dimensions, though it may appear a sharp edge to the unassisted senses.

The imperfection of the definite arithmetical definition of proportion is universally admitted, while the complexity of the rigorous definition by which Euclid supplied its place is almost as universally felt to be a grievance. Many attempts have been made to avoid the trouble without incurring the reproach of inaccuracy. One or two of these we shall notice.

Legendre, in his otherwise excellent work on geometry, refers the student to works on arithmetic for the theory of proportion; and, having stated that when A is to B as C to D, it is known that A × D = B × C, adds (twelfth edition, page 61), "This is certainly true for numbers; it is true also for any magnitudes, provided they can be expressed, or that we imagine them expressed by numbers, and this we may always suppose." A system of geometry which tells the learner in so many words that he may always suppose that which is not true, needs no further comment, even though Legendre were its author. It is true that in subsequent parts of the work we find demonstrations adapted to the case of incommensurable quantities, but they want that most important element of a proposition involving proportions, namely, a definition of what the term means; these demonstrations turn upon the theorem that when four quantities are proportional, the first is greater than, equal to, or less than the second, according as the third is greater than, equal to, or less than the fourth; but it has not been previously stated what the author means by four quantities being proportional. In the English translation of the preceding work, a preliminary chapter is added on proportion, in which the definition given as to incommensurable magnitudes amounts to the following:—when A and B are incommensurable, and also C and D, the four are said to be proportional when A′ and C′ can be found, as near as we please to A and C, and which, being commensurable with B and D, are proportional to them, in the arithmetical sense of the term. This is a sufficient definition; but it really amounts to that of Euclid (as do all sufficient definitions which we have seen), and is not so easily used.

M. Lacroix ('Elémens de Géométrie,' p. 5) makes the approximate finding of a common measure stand in place of an exact process, and, fairly stating that the error of the process may be made too small to be visible, rests the exactness of his geometry on its not being sensibly erroneous.

The author of the 'Elements of Geometry,' in the 'Library of Useful Knowledge,' states the proportion of incommensurable magnitudes to consist in "their ratios admitting of being approximately represented by the same numbers, *to how great an extent soever* the degree of approximation may be carried." In virtue of the words in italics, this definition may be considered as being, when properly used, capable of forming the basis of an exact theory; and that it is properly used in the work cited we fully admit, since its first application is to the establishment of the definition of Euclid. The only objection we should make to the work in question is that its expressions (page 48) would lead the student to imply that commensurability is the general rule, and incommensurability the exception; an extended theory is given, because magnitudes are not always commensurable. Now it is important the student should know, and should always bear in mind, that of two magnitudes of the same kind taken at hazard, or one being given and the other deduced by a geometrical construction, it is very much more likely that the two should be incommensurable than that they should be commensurable. So that the apparently cumbrous theory of proportion is not introduced to meet a few cases which sometimes occur, but to prevent the majority of instances from being treated incorrectly.

The definition[*] of proportional quantities given by Euclid is as follows:—"Magnitudes are said to have the same ratio to one another, the first to the second, and the third to the fourth, when equimultiples of the first and third, and equimultiples of the second and fourth, whatever the multiplications may be, yield a multiple of the first, greater than, equal to, or less than, that of the second, according as the multiple of the third is greater than, equal to, or less than, that of the fourth." That is, if A, B, C, and D be the four magnitudes, and m and n any two whole numbers whatsoever, m A must be greater than, equal to, or less than n B, according as m C is greater than, equal to, or less than n D. Otherwise thus: whatever whole numbers m and n may be, A must exceed, equal, or fall short of n-$m$ths of B, according as C exceeds, equals, or falls short of n-$m$ths of D. A person practised in algebra would comprehend the definition most easily when stated thus: $m\mathrm{A} - n\mathrm{B}$ must have the same sign as $m\mathrm{C} - n\mathrm{D}$, for all whole values of m and n.

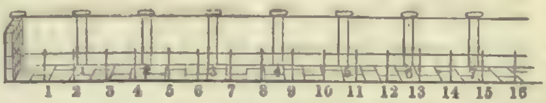
This definition equally applies whether A and B be commensurable or incommensurable, since no attempt is made to measure B by an aliquot part of A. The two questions which must be asked, and satisfactorily answered, previously to its reception, are as follows:—

1. What right had Euclid, or any one else, to expect that the preceding most prolix and unwieldy statement should be received by the beginner as the definition of a relation the perception of which is one of the most common acts of his mind, since it is performed on every occasion where similarity or dissimilarity of figure is looked for or presents itself?

2. If the preceding question should be clearly answered, how can the definition of proportion ever be used; or how is it possible to compare every one of the infinite number of multiples of A with every one of the multiples of B?

To the first question we reply, that not only is the test proposed by Euclid tolerably simple, when more closely examined, but that it is, or might be made to appear, an easy and natural consequence of those fundamental perceptions with which it may at first seem difficult to compare it. To elucidate this, suppose the following case:—

There is a straight colonnade composed of columns at equal distances from each other, the first being distant from a bounding wall by a length equal to the distance between any two successive columns. In front of the colonnade let there be a row of railings[*] equidistant from each other, the first being at the same distance from the wall at which the railings are from each other. Let the columns be numbered from the wall, and also the railings; remember also that it is not supposed that there goes any exact number of railings to the interval of two columns, but that the interval of the columns may be to the interval of the railings in any ratio, commensurable or incommensurable.



If we may suppose this construction carried on to any extent, it is easily shown that a spectator, by mere inspection, without measurement, may compare the column-distance (C) with the railing-distance (R), to any degree of accuracy. For example, since the tenth railing falls between the fourth and fifth columns, it follows that 10 R is greater than 4 C and less than 5 C, or that R lies between $\frac{4}{10}$ of C and $\frac{5}{10}$ of C. To get a more accurate notion, he may examine the 10,000th railing: if it fall between the 4674th and 4675th columns, it follows that 10,000 R lies between 4674 C and 4675 C, or R lies between $\frac{4674}{10000}$ and $\frac{4675}{10000}$ of C. There is no limit to the degree of accuracy thus obtainable; and it can also be shown that the ratio of C and R is determined when the order of distribution of the railings among the columns is assigned *ad infinitum*; or, which is the same thing, when the position of *any* given railing can be found, as to the numbers of the columns between which it lies. Any alteration, however small, in the place of the first railing, must at last affect the order of distribution. Suppose, for instance, that the first railing is moved farther from the wall by one part in a thousand of the distance between the columns; the second railing must then be pushed forward twice as much, the third three times as much, and so on: those after the thousandth are pushed forward more than a thousand times as much,—that is, by more than the interval between the columns,—or the order with respect to the columns is disarranged.

Let it now be proposed to make a model of the preceding construction, in which c shall be the distance between the columns, and r that between the railings. It needs no definition of proportion, nor anything more than the conception which we have of that term prior to definition (and with which we must show the agreement of any definition we may adopt), to assure us that C must be to R in the same proportion as c to r, if the model be truly formed. Nor is it drawing too largely on that conception of proportion if we assert that the distribution of the railings among the columns in the model must be everywhere the same as in the original: for example, that the model would be *out of proportion* if its 56th railing fell between the 18th and 19th columns, while the 56th railing of the original fell between the 17th and 18th columns. Here, then, the question as to the dependence of Euclid's definition upon common notions is settled; for the obvious relation between the construction and its model which has just been described contains the collection of conditions, the fulfilment of which, according to Euclid, constitutes proportion. According to Euclid, whenever m C exceeds, equals, or falls short of n R, then mc must exceed, equal, or fall short of nr: by the most obvious property of the preceding constructions, according as the mth column comes after, opposite to, or before the nth railing, in the original, th mth column must come after, opposite to, or before the nth railing, in the correct model.

That the test proposed by Euclid is necessary, appears from the preceding; and also that it is sufficient. For, admitting that, to a given original, with a given column-distance in the model, there is one correct model railing-distance (which must therefore be the one which distributes the railings among the columns as in the original); we have seen that any other railing-distance, however slightly different, would at last give a different distribution: that is, the correct distance, and the correct distance only, satisfies all the conditions required by Euclid's definition.

---

[*] The Greek of Euclid's definition is very short, and can only be intelligibly rendered into English by circumlocution. Ἐν τῷ αὐτῷ λόγῳ μεγέθη λέγεται εἶναι, πρῶτον πρὸς δεύτερον καὶ τρίτον πρὸς τέταρτον, ὅταν τὰ τοῦ πρώτου καὶ τρίτου ἰσάκις πολλαπλάσια τῶν τοῦ δευτέρου καὶ τετάρτου ἰσάκις πολλαπλασίων, καθ᾽ ὁποιονοῦν πολλαπλασιασμὸν, ἑκατέρου ἢ ἅμα ἐλλείπῃ, ἢ ἅμα ἴσα ᾖ, ἢ ἅμα ὑπερέχῃ ληφθέντα κατάλληλα.

[*] By the terms column and railing we mean throughout to designate vertical lines which are the axes of the columns or railings.

Let us now, by the *distribution* of one set of magnitudes among those of another set, agree to mean the placing of the first magnitudes among those of the second set, the latter having been previously arranged in ascending order of magnitude. Thus, in the following instance, we distribute the multiples of 3 among those of 8, the latter being in Roman numerals:—

3 6 viii 9 12 15 xvi 18 21 xxiv 27 30 xxxii &c.
24

This use of the word distribution having been well learnt, the following way of stating the definition will be easier than that of Euclid:—"Four magnitudes—A and B of one kind, and C and D of the same or the same other kind—are proportional when all the multiples of A are distributed among the multiples of B in the same intervals as the corresponding multiples of C among those of D." Or, whatever numbers m and n may be, if m A lie between n B and $(n+1)$ B, m C lies between n D and $(n+1)$ D.

If the preceding test be always satisfied from and after any given multiples of A and C, it must be true before those multiples. For instance, let the test be always satisfied from and after 100 A and 100 C; and let 5 A and 5 C be instances for examination, falling before 100 A and 100 C. Take some multiple of 5 which will exceed 100, say 50 times, and let it be found on examination that 250 A lies between 678 B and 679 B; then 250 C lies between 678 D and 679 D. Divide these by 50, and it follows that 5 A lies between $13\frac{28}{50}$ B and $13\frac{29}{50}$ B, and still more between 13 B and 14 B. Similarly, 5 C lies between $13\frac{28}{50}$ D and $13\frac{29}{50}$ D, and still more between 13 D and 14 D. Or 5 A lies in the same interval among the multiples of B in which 5 C lies among the multiples of D; and the same demonstration applies to any other instance.

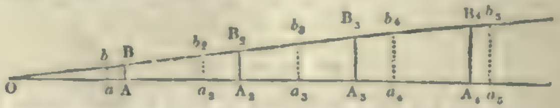
Again, the test is also satisfied if the multiples of any multiple (m) of A are distributed among the multiples of any multiple (n) of B in the same manner as the multiples of m C among the multiples of n D: for instance, if the multiples of 3 A be distributed among those of 5 B in the same manner as the multiples of 3 C among those of 5 D. Let 11 A and 11 C be given for examination; take any multiple of 3 greater than 5, say 3 × 3, or 9, and examine 11 (9 A) and 11 (9 C), or 33 (3 A) and 33 (3 C). Let 33 (3 A) lie between 27 (5 B) and 28 (5 B); then by hypothesis 33 (3 C) lies between 27 (5 D) and 28 (5 D). Divide all by 9, and we find that 11 A lies between 15 B and $15\frac{5}{9}$ B, while 11 C lies between 15 D and $15\frac{5}{9}$ D. Hence 11 A lies between 15 B and 16 B, while 11 C lies in the same interval among the multiples of D; and in the same manner any other instance may be proved.

The principles of the fifth book of Euclid are by many supposed to be inevitably connected with the apparatus of straight lines drawn parallel to one another, by which Euclid represents his magnitudes and their multiples. This is not the case; and the simple expression of magnitudes by large letters, and of numerical multipliers by small ones, will very much facilitate the demonstrations, without altering anything but mere modes of expression.

The next point to be considered is the infinite character of the definition of proportion; four magnitudes are not to be called proportional, until it is shown that every multiple of A falls in the same interval among the multiples of B, in which the same multiple of C is found among the multiples of D. So that this definition is a negative one, like that of parallel lines, which may be thus stated: two lines are parallel when every point of one of them, however far produced, is on one side of the other. We might expect then to find that the test of *disproportion* is simple and positive, and an examination of the illustration already produced will confirm this.

Suppose that the distribution of the railings among the columns should be found to agree in the model and the original as far as the millionth railing. This proves, as we have seen, only that the railing-distance of the model does not err by the millionth part of the corresponding column distance; for if it did err so much, the multiplication of the error a million-fold would have placed the millionth railing (if none before it) wrong by at least one interval. It is then obvious that no examination of individual cases, however extensive, will enable an observer of the construction and its model to affirm the proportion or deny disproportion: all that it can do is to enable him to fix limits (which he may make as small as he pleases) to the disproportion, if any. But a single instance may enable him to deny proportion or affirm disproportion, and also to state which way the disproportion lies. Let the 19th railing in the original fall beyond the 11th column, while the 19th railing of the (so-called) model does not come up to the 11th column. It follows from this one instance, that the railing-distance of the model is too small relatively to the column-distance, or that the column-distance is too great relatively to the railing-distance; that is, the proportion of r to c is less than that of R to C, or the proportion of c to r is greater than that of C to R. Similarly, with respect to two straight lines, no examination of pairs of points, one in each, will enable the examiner to affirm their parallelism or deny their intersection; while, at the same time, the examination of one pair of points may enable him to affirm intersection or deny parallelism. Hence it appears that, obvious as the notion of proportion may be, it is more easy, in a mathematical point of view, to define disproportion, and to make proportion consist in the absence of all disproportion. Similarly, obvious as is the notion of parallelism, and the connection of the non-intersection of two straight lines with that of their always keeping the same distance with each other, it is more easy to define this relation by the absence of all intersection than by any of its positive properties.

The negative character of the definition of parallels does not prevent it from being very easily proved that such lines exist; and an examination of the first or last propositions of the sixth book of Euclid will show that the existence of proportional quantities is as easily established on the definition given as on any other. To take an instance, however, in which nothing but lines shall be the objects of consideration, we shall here prove, in a different manner, the second proposition of Euclid's sixth book, or one to the same effect.



Let O A B be a triangle, to one side of which ab is drawn parallel, and in O A produced set off A A_2, $A_2 A_3$, &c., equal to O A, and $a\,a_2$, $a_2 a_3$, &c., equal to O a. Through every one of the points so obtained draw parallels to A B, meeting O B produced in b, b_2, B_2, &c. Then it is easily proved that $b\,b_2$, $b_2 b_3$, &c., are severally equal to O b, and B B_2, $B_2 B_3$, &c., to O B. Consequently a distribution of the multiples of O A among those of O a is made on one line, and of O B among those of O b on the other. The examination of this distribution in all its extent (which is impossible, and hence the apparent difficulty of using the definition) is rendered unnecessary by the known property of parallel lines. For since A_3 lies between a_3 and a_4, B_3 must lie between b_3 and b_4; for if not, the line $A_3 B_3$ would cut either $a_3 b_3$ or $a_4 b_4$. Hence, without inquiring where A_m *does* fall, we know that if it fall between a_n and a_{n+1}, B_m must fall between b_n and b_{n+1}: or if m × O A fall in magnitude between n × O a and $(n+1)$ × O a, then m × O B must fall between n × O b and $(n+1)$ × O b. Thus it is established that O A is to O a as O B to O b.

The propositions of the fifth book become very simple when the definition is fully elucidated, and symbolic expression is substituted for the words at length of Euclid. They will be found thus treated in Playfair's or Lardner's editions of Euclid, and in the 'Connection of Number and Magnitude' (London, 1836).

When quantities are commensurable, a multiple of one may be found which is exactly equal to a multiple of the other: thus if A = $3\frac{4}{13}$ B, 13 A = 43 B. In this case the arithmetical definition of proportion is sufficient, and the other may be shown to follow from it. Let A = $3\frac{4}{13}$ B, and C = $3\frac{4}{13}$ D, so that, arithmetically speaking, A is to B as C to D. Let m A lie between n B and $(n+1)$ B, or $(3\frac{4}{13}m)$ × B lies between n B and $(n+1)$ B. Then the number or fraction $3\frac{4}{13}m$ must lie between n and $n+1$; whence $(3\frac{4}{13}m)$ D lies between n D and $(n+1)$ D, or m C lies between n D and $(n+1)$ D.

It is however perfectly allowable to leave out of sight the possible case in which a multiple of A is exactly equal to a multiple of B; since if the test be true in all other cases, it is therefore true in this. For, if possible, let 4 A = 7 B, and 4 C be (say) greater than 7 D. Then m (4 C) exceeds m (7 D) by m times this difference, which may be made as great as we please, or 4 m C, and multiples succeeding it, may be made to fall in an interval as many intervals removed from that of 7 m D and $(7m+1)$ D as we please. But 4 m A is equal to 7 m B, whence $(4m+1)$ A, &c., must fall among the multiples of B in intervals of given nearness[*] to the interval of 7 m B and $(7m+1)$ B. Consequently the multiples of A following 4 m A cannot always fall among the multiples of B in the same intervals as the same multiples of C among those of D; and the rest of the test cannot be true, unless 4 C = 7 D; that is, if the rest of the test be true, then 4 C = 7 D.

The following question will enable the reader to see for himself how far he is able to apply the method of Euclid:—Returning to the illustration, suppose that the columns, instead of being mathematical lines, are of a given thickness, and that the columns in the model are of a proportionate thickness; let it also be supposed that when a railing is projected upon the column, there are no means of determining on which side of the axis of the column it falls. It is to be shown that if the distribution be according to the definition as to every railing which is not so projected, and about which there is therefore no doubt, it must also be true as to every case in which the doubt exists.

The advantages of the study of proportion in the manner laid down by Euclid, or some other equivalent in extent and strictness, are precisely the advantages of accuracy over inaccuracy, and of real demonstration over a false and slovenly appearance of it, which, though a close resemblance, is therefore all the more dangerous. And it must be remembered what we mean by demonstration, namely, the process of obtaining a conclusion by sound logic from premises known to be true. If the prolixity of Euclid's method could be avoided by an assumption, we should not object, provided the assumption were both true and easily seen to be true. For instance, if the theory of PARALLELS could be established without its axiom by means of a hundred long and intricate propositions, we should agree with those who would refuse to place those propositions before beginners, on the ground that unimpeachable demonstration is already given, namely, an assumption which those who would rather dispense with it do not deny to be both true and easy (or capable of being made easy), and logic which is uncontested and incontestable. But the vice of the system which is substituted for that of Euclid, consists in the entrance of an assumption which is *not* true; for to reason upon all magnitudes as if they were commensurable, and to assert conclusions derived from such reasonings, is to assume that all magnitudes are commensurable, which is not true. The method of Lacroix, as above explained, is sound as far as it goes: he asserts that the propositions of geometry are sensibly true, or if false, imperceptibly false, and this he proves. But he makes geometry cease to be an exact science. That of Legendre, on the other hand, though it proves no more than that of Lacroix, professes to prove more: it treats geometry as an exact science, while it avowedly states that an assumption may be made which is demonstrably incorrect.

---

[*] We leave the reader to put this demonstration into a more exact form.

We do not deny that a mind well versed in the doctrine of limits would have a process of its own, by which it would rigorise the method of Lacroix, arguing as follows:—The same means which show the propositions of geometry to have no error perceptible to our senses, would also show them to have no error perceptible to any imperfect senses, however near to perfection they might be; and that error which is less than any assignable error, must be no error at all. All this, when properly extended, we might admit; but how are we to suppose, in the student who has just left the fourth book of Euclid, a perception of the truths of the doctrine of limits, the notorious want of which creates the difficulties of the differential calculus? Sound teaching makes a true theory of proportion one, out of many previous helps, to the attainment of the differential calculus: but the inversion of the process not only adds difficulty to the latter, by intercepting proper illustration, but introduces falsehood into the former; and such teaching is the most vicious of all vicious circles, because it propagates its kind.

The mathematical writers of this country have, taken altogether, shown a superiority in exactness of demonstration over those of any other of modern times, and the deep and early root which the sound principles of Euclid have taken has been mainly the cause of this. If those principles be abandoned, that superiority will cease to exist; but this of itself would be of little consequence; not so the loss of a large amount of formation of accurate habits, which would certainly follow the substitution of a gross and (so called) practical instrument of calculation for an exact and liberal science.

Those to whom the mathematical sciences are taught as aids to the power of distinguishing truth from falsehood, logic from fallacy, the exact consequence from all incorrect inference, very many times exceed in number those who only wish for an instrument to be used in the study of physics and the arts of life. If then practical mathematics mean those mathematics which best answer the purpose of the great majority of learners, the more they are rigorous the more they are practical. But the enticing word *practical* has been otherwise appropriated; and "exact enough for practical purposes" is the phrase applied to many a result of which the practical use belongs to the astronomer, mechanician, surveyor, engineer, or computer. To such a meaning of the word practical there is no objection as opposed to liberal or disciplinatory, when it is *knowledge* or *science* which is spoken of; but as applied to *art*, practical is opposed to unpractical, which cannot be carried into practice, or useless, for that which cannot be practised is useless in art. But those who would consider the use of knowledge in steadying the mind and making it a judge between the true and the false, and a safe guide to the methods of finding truth, must beware, in mathematics, how they allow the notions which art attaches to the word practical any influence over their method of studying science. For want of such a caution many have missed all comprehension of the higher branches even of the art to which they aspired, to say nothing of the loss of that science to which it should seem they did not mean to aspire.

PROPORTION, in Music, is either *Harmonical* or *Rhythmical*.

Harmonical Proportion is when, of three numbers representing the relations of sounds, the first has the same proportion to the third as the difference between the first and second has to the difference between the second and third; as in the numbers 6, 8, 12; where

$$6 : 12 :: 8-6 : 12-8;$$

that is to say, $6 : 12 :: 2 : 4.$

When four numbers are in Harmonical Proportion, then the first has the same proportion to the fourth as the difference between the first and second has to the difference between the third and fourth; as in the numbers 6, 8, 12, 18; where

$$6 : 18 :: 8-6 : 18-12;$$

that is to say, $6 : 18 :: 2 : 6.$

The proportions of the sounds of the diatonic scale [DIATONIC] are as follows:—

The Key-note	1 : 1
2nd	9 : 8
3rd (major)	5 : 4
4th	4 : 3
5th	3 : 2
6th	5 : 3
7th	15 : 8
8th, or octave	2 : 1

[SCALE; ACOUSTICS.]

Rhythmical Proportion is the proportion, in relation to time or measure, between the notes representing duration. Thus, the semibreve to the minim is 2 : 1; the semibreve to the crotchet, 4 : 1; the minim to the semiquaver, 8 : 1; &c. That is, the semibreve is twice as long in time as the minim; four times as long as the crotchet, &c.

PROPORTIONAL COMPASSES. [COMPASSES.]

PROPORTIONAL LOGARITHMS, also called logistic logarithms. [TABLES.] Suppose it frequently required to calculate the fourth term of a proportion of which the first term is one given quantity, say A: that is, required a fourth proportional to A, p, and q. Common logarithmic calculation here requires three inspections of the table, one addition, and one subtraction. But if A be always the same thing, a new table may be framed, which shall only require two inspections and one addition, as follows:—Opposite to p in the table, write $\log A - \log p$ instead of $\log p$, and call the former the proportional logarithm of p, which must be considered as the abbreviation of "logarithm of p proper to be used in proportions of which the first term is A." The rule then is;—to find a fourth proportional to A, p, and q, add the proportional log of p to that of q, and the sum is the proportional logarithm of the answer. For $\log A - \log p$, and $\log A - \log q$, added together, give

$$\log A - \log \frac{pq}{A};$$

which is, by definition, the proportional logarithm of $pq \div A$, the answer required.

In tables made to be used with the old Nautical Almanac, in which the moon's motion was given for every three hours, A was made $= 3^h = 10800^s$; and p and q were given in the table, not in seconds, but reduced to hours, minutes, and seconds. Thus the question—

$$3^h : 1^h\,23^m\,18^s :: 14^m\,13^s : x,$$

could be answered, and x found, by two inspections and an addition. But the convenience of this table lay much more in the arrangement into hours, minutes, and seconds, than in the nature of the substitute for the logarithm: and since a similar arrangement is now made to accompany common tables of logarithms, it may be doubted whether the day of logistic logarithms be not past.

PROPORTIONAL PARTS, a name given in logarithmic and other tables to small tables which are annexed to the differences of the tabular number, and which consist merely in setting down the several tenths of the differences or the nearest whole numbers to them. Thus, in the case of 953, the table of proportional parts is as follows:—

953

1	95
2	191
3	286
4	381
5	477
6	572
7	667
8	762
9	858

Thus, 286 is the whole number nearest to 3-tenths of 953; from which we infer that 29 is the whole number nearest to 3-hundredths of 953. If then we would have ·74 of 953 to the nearest whole number, we take

7 tenths . 667
4 hundredths . 38
705

or 705 is the nearest whole number required, subject to the possibility of an error of a unit, which is of no consequence in the matters for which such tables are used. This is the process required in logarithmic interpolation, when tables of seven decimal places are used. Makers of tables now begin to give complete multiples, with one figure separated, as by a comma.

PROPORTIONS, DEFINITE. [ATOMIC THEORY.]

PROPOSITION. [ORGANON.]

PROPYL (C_6H_7), sometimes called *trityl*—from τρίτος, *third*—is the third organic radical in the series C_nH_{n+1}. It is the assumed root of the members of the propylic, or tritylic, group of organic compounds. The following are the only members of the propylic group at present known.

Propylene (C_6H_6). *Tritylene*. This gas is one of the products of the decomposition of amylic alcohol on passing through a red hot porcelain tube. It is most readily prepared by distilling one part of iodopropylene with five of mercury and two of concentrated hydrochloric acid, It is evolved in a tolerably copious stream, one ounce of iodopropyl yielding more than 150 cubic inches of gas.

Propylene has a peculiar odour somewhat resembling olefiant gas, a sweetish suffocating taste, and a sp. gr. of 1·498. It is tolerably soluble in alcohol, but water absorbs only about one-eighth of its bulk. It may be liquified by great pressure.

Iodo-propylene, or *iodide of allyl* (C_6H_5, I) is formed on distilling a mixture of equal parts of iodide of phosphorus and syrupy glycerin. It is a colourless liquid of sp. gr. 1·789, of ethereal alliaceous odour, a sweet but irritating taste, insoluble in water, but soluble in alcohol or ether. It rapidly becomes brown on exposure to air.

Iodide of propylene (C_6H_6, I_2). At a slightly elevated temperature, iodine absorbs propylene and forms a colourless liquid of ethereal odour, and density 2·49. It rapidly decomposes in contact with air.

Chlorides and *bromides of propylene.* Chlorine and bromine act upon propylene in much the same way as upon ETHYLENE, and the resulting compounds yield chlor- or brom-propylenes when treated with alcoholic potash. The following are the compounds referred to :—

Name.		Boiling point.	Density.
Chloride of propylene . . .	C_6H_6, Cl_2	219·2	1·151
Chlor-propylene	C_6H_5Cl		
Chloride of chlor-propylene .	C_6H_5Cl, Cl_2	338	1·347
Bichlor-propylene . . .	$C_6H_4Cl_2$		
Chloride of bichlor-propylene	$C_6H_4Cl_2, Cl_2$	333 to 392	1·548
Trichlor-propylene . . .	$C_6H_3Cl_3$		
Chloride of trichlor-propylene	$C_6H_3Cl_3, Cl_2$	428 to 437	
Quadrichlor-propylene . . .	$C_6H_2Cl_4$		
Chloride of quadrichlor-propylene	$C_6H_2Cl_4, Cl_2$	464 to 473	1·731
Quintichlor-propylene . . .	C_6HCl_5		
Chloride of quintichlor-propylene .	C_6HCl_5, Cl_2	500	1·731
Sexchlor-propylene . . .	C_6Cl_6		
Chloride of sexchlor-propylene	C_6Cl_6, Cl_2	536	1·860
Bromide of propylene . . .	C_6H_6, Br_2	293	1·974
Bromo-propylene . . .	C_6H_5Br	143·6	1·472
Bromide of bromo-propylene . .	C_6H_5Br, Br_2	377·6	2·336
Bibromo-propylene . . .	$C_6H_4Br_2$	248	1·950
Bromide of bibrom-propylene . .	$C_6H_4Br_2, Br_2$	439	2·469
Tribrom-propylene . . .	$C_6H_3Br_3$		
Bromide of tribrom-propylene . .	$C_6H_3Br_3, Br_2$	491	2·601

Hydrate of propyl, or *propylic alcohol* (C_6H_7O, HO), is contained, along with amylic alcohol, in the last portions of the distillate in the first rectification of spirits of wine. It is separated by fractional distillation. It is a limpid liquid, lighter than water, and of agreeable fruity odour. It is very soluble in water, and boils at about 205° Fahr.

Chloride of propyl (C_6H_7, Cl). Fuming hydrochloric acid slowly absorbs propylene at 212° Fahr.; on saturating the liquid with carbonate of soda, chloride of propyl is obtained. It is a liquid lighter than, and insoluble in, water; boils at 104° Fahr., and in odour, taste, and inflammability, much resembles chloride of ethyl.

Propyl-sulphuric acid (C_6H_7O, HO, S_2O_6) is formed on mixing propylic alcohol with sulphuric acid. Diluted with eight or ten times its bulk of water, saturated with carbonate of potash, evaporated to dryness, the residue dissolved in boiling absolute alcohol and set aside, furnishes acicular crystals of *propyl-sulphate of potash* (C_6H_7O, KO, S_2O_6).

Propylamine $\left(\left.\begin{matrix}C_6H_7\\H\\H\end{matrix}\right\}N\right)$. *Tritylamine. Metacetamine. Onylamine.* This body is formed on acting upon iodopropylene with ammonia; it may be extracted by caustic potash. It is an oily body very soluble in water, of ammoniacal odour and alkaline reaction. It boils between 122° and 140° Fahr. It combines with acids to form salts: the *chloroplatinate* contains ($C_6H_9N, HCl, PtCl_2$).

Arsenide of propyl. One of the products of the distillation of a mixture of arsenious acid and dry butyrate of lime appears to be arsenide of propyl, but it has not been thoroughly examined. It does not ignite spontaneously.

PROPYLÆUM (προπύλαιον: the great entrance to the Acropolis of Athens was called προπύλαια, in the plural number; Thucydides, ii. 13), signifying literally a fore-portal or one detached from and placed in advance of the building to which it gave access, is used as a distinctive term for the structures through which was the entrance into the enclosure surrounding some of the Grecian temples. Unlike the vast truncated pyramidal masses or moles that enclosed the forecourt of Egyptian temples, on the entrance side, leaving only a lofty square-headed portal for access, thereby screening the main edifice and colonnades within the court, and giving the exterior the aspect of a fortress,—the propylæa of the Greeks were detached structures placed in advance of the sacred edifice itself, so as to mark very conspicuously the approach to it through the outer enclosure or boundary. They seem to have been intended in some degree to prefigure the temple to which they conducted; their general appearance in front being almost identically the same as that of the frontispiece-façade or pediment end of a prostyle temple.

The general arrangement and character of a Greek propylæum may be described as similar to those of an amphiprostyle temple [TEMPLE], shorter however on its sides than the width in front, and without any *cella*, yet not entirely open to both fronts, but divided by an inner wall across it from side to side, into two portions, the outer one of which, answering to the *pronaos* of a temple, was larger than the other; so that the whole may be more briefly, if not more intelligibly explained, by comparing the plan to the *pronaos* and *opisthodomus* of an amphiprostyle temple, put together without any intervening cella, being separated only by the wall above mentioned, in which were as many open doorways as there were intercolumns in front.

Such was the disposition of the propylæa both of the Parthenon at Athens and of the temple at Eleusis, the only two examples of such structures known to us, and the latter now so only by the drawings of it in the unedited antiquities of Athens: there were, indeed, as we learn from Pausanias (ii. 3) propylæa at Corinth, but of their architectural design we know nothing. The Athenian structure stands on the west side of the Acropolis, but is not on the same axis or line as the temple. This propylæum, which was begun by the architect Mnesicles in the 4th year of the 85th olympiad, and completed in five years, is of the Doric order, and hexastyle on both fronts; and the outer or western one was greatly extended by two flanking wings projecting forward at right angles, so as to enclose the platform to which an ascent of steps led up from below, and above which the portico and the two lesser colonnades forming the sides of the wings were raised upon three other steps. Thus the platform (78 feet from north to south, by 40 east and west) became an elevated open fore-court, presenting a principal portico in front crowned by a pediment, and two colonnades, which being considerably lower (their columns 19 feet, the others 28½ feet high) gave greater importance to the former; and a degree of scenic effect—combination, contrast, and variety—was produced, very unusual in Grecian architecture.

One of the most remarkable circumstances which served to distinguish the Propylæa from a portico is that in the outer division there were two rows of inner columns placed not parallel with, but at right angles to the columns in front, and in a line with the two middle ones, thereby dividing the plan internally into three compartments, the centre one narrower than the other two, and forming an avenue to the principal doorway, which was the largest and loftiest of the five openings in the transverse wall, and the two end ones the smallest. These inner columns, too, instead of being of the same order as the exterior, were Ionic,—a very remarkable peculiarity, inasmuch as it evidences an intermingling of styles almost unknown to Grecian architecture. The licence—so to call it—was, however, fully justified by the circumstances of the case, because columns of lesser diameter than the external ones were required, and also of such height as to reach the architrave soffits of the internal ceiling, which are in a line with the top of the architrave of the external order.

The Eleusis propylæum resembled that of the Acropolis in nearly all particulars, except that it had no wings attached to it. Like the Athenian one, it was of the Doric order, hexastyle on both fronts, and had six Ionic columns within, similarly in two rows.

As modern structures partaking of the ancient Greek propylæum character, may be mentioned Cagnola's Porta Ticinense at Milan, and the London terminus of the London and North-Western Railway, in Euston Square, which, though only a distyle in antis in both fronts, is a fine example of Grecian Doric upon a scale of extraordinary magnitude. Both the modern examples, however, differ from the ancient ones in being entirely open, without any internal transverse wall; and the Italian one has, moreover, a large open arch on each side, forming a passage through it in that direction.

PROPYLAMINE. [ORGANIC BASES; PROPYL.]

PROPYLENE. [PROPYL.]

PROROGATION. [PARLIAMENT.]

PROSE comprehends any species of composition which is not written in metre. Modern writers have differed much respecting what constitutes the distinction between prose and poetry. Some writers maintain that the whole class of compositions, which have pleasure for their *main* object, ought to be regarded as poetry; but Whately, on the other hand, contends that metre is the essence of poetry, and consequently defines poetry as "elegant and decorated language, in metre, expressing such and such thoughts," and good prose-composition "such and such thoughts expressed in good language" ('Rhetoric.') [POETRY.]

PROSELYTE (*προσήλυτος*, connected with *προσέρχομαι, to come to*), a new comer. This word is not found in classical Greek, but occurs many times in the Septuagint, and a few times in the New Testament. It answers to the Hebrew, גֵּר, a stranger. "Proselytes," says Suidas, "are they who have come out of the Gentiles, and live according to the divine laws." The word is applied almost exclusively to persons converted to the religion of the Jews. It is now usually applied to converts from one religion or religious sect to another, but is occasionally used in reference to political theories.

PROSERPINA. [PERSEPHONE.]

PROSERPINE. [ASTEROIDS.]

PROSODY (προσῳδία) is derived from a Greek word, which has exactly the same meaning as the Latin *accentus*, and was used by the Greeks in the same sense. (Quintil., 'Inst. Orator,' i. 5; Aulus Gellius, xii. 6.) Most modern writers however make a distinction between prosody and accent, understanding by the former what is usually called *quantity*, that is, the duration of a sound. Thus it is said that the principle of Greek and Roman versification is *quantity*, while that of the poetry of the modern European languages depends on *accents*. It is not however improbable that what the ancients meant by *quantity* was not very different from what we call *accent*. [Accent.] The subject is well treated in an able article in the fourth volume of the 'Journal of Education,' published under the superintendence of the Society for the Diffusion of Useful Knowledge, 1832.

PROTECTION ACTS. The object of these statutes is to enable a debtor in insolvent circumstances to avert or forestall the impending danger of imprisonment; for any person not a trader within the Bankrupt Acts, or who, being a trader, owes less than 300*l*., whether in prison or not, may apply in London to the Insolvent Court, in the country to the County Courts, for protection from process. A *schedule* of debts, and of the names of his creditors, must accompany the petition; which must set forth an account of his whole estate and liabilities, and be verified by affidavit.

On the petition being filed, the court makes an *interim order*, which protects the petitioner from all civil process until his *examination*, but he may still be arrested under a judge's order, to hold him to bail. If in prison, the order effects the petitioner's discharge. The presentation of the petition vests all the petitioner's effects in the registrar, who, as *official assignee*, proceeds to possess himself of all that can be obtained without suit. Notice of the petition is given to the creditors, and inserted in the 'Gazette' and local newspapers, a public sitting of the court being at the same time appointed for the first examination of the petitioner. If it appear that the allegations in the petition and the matters in the schedule are true, and that the debts have not been contracted fraudulently or improperly, and do not arise from any of the acts of misconduct enumerated in the statutes, a day is fixed on which a *final order* shall be made, unless cause be shown to the contrary. If made, its effect is to permanently protect the petitioner from all process, in respect of the debts due, at the time of filing the petition, to the creditors named in the schedule. On the other hand, if cause is shown, the court may adjourn the consideration of the final order *sine die*, or dismiss the petition.

At any time *after* the final order, the assignees of the estate may claim property since acquired by the insolvent, which claim may be summarily enforced by the order of the court. So that under the Protection Acts, as in the case of an insolvency, the *future* as well as *present* property of the debtor may be applied in payment of his debts. In this consists the great distinction between the relief afforded by the bankrupt laws to a *trader*, and that obtainable by an *insolvent debtor*, or a petitioner under the Protection Acts.

(Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. ii. p. 516.)

PROTECTOR. [Settlement.]

PROTEIN, a substance obtained by Mulder from albumen, casein, horn, and animal and vegetable fibrin. When any one of these is dissolved in a solution of potash, and the filtered solution is mixed with a slight excess of acid, a copious grayish-white, flocculent precipitate is formed, and a slight smell of hydrosulphuric acid is perceived. This white substance is *protein*, so called from its occupying the first or most important place in relation to the albuminous principles.

Its properties are:—While moist the white flocculi are diaphanous, but by drying they become yellowish, hard and brittle. It possesses neither smell nor taste, attracts moisture rapidly from the air, and loses water at 212°. It is insoluble in water, alcohol, ether and essential oils. By long continued boiling in water it undergoes some change of properties, and is rendered soluble.

Acetic and phosphoric acids, whatever may be their state of concentration, dissolve it; hydrochloric acid also dissolves protein, and acquires an indigo tint. When heated the solution blackens. With concentrated sulphuric acid it produces a jelly which contracts in water, and which, after being washed with water and alcohol, though it does not redden litmus-paper, contains 8·34 per cent. of sulphuric acid. Mulder calls this compound *Sulphoproteic acid*. When protein is boiled in dilute sulphuric acid, it acquires a purple tint.

Protein is precipitated from its acid solutions by the ferro and ferridcyanide of potassium, by tannin, and by neutralisation with an alkali. When strongly heated, protein is decomposed with the production of ammonia and a charcoal which burns with difficulty, but leaves no residue.

Protein consists entirely of carbon, hydrogen, nitrogen, and oxygen; and it will be observed, that whether obtained from albumen (1), casein (2), horn (3), animal fibrin (4), or vegetable fibrin (5), the statements of its composition differ so slightly, as to show that it must be the same from whichsoever of the sources named it is procured.

	(1)	(2)	(3)	(4)	(5)
Carbon . .	55·30	55·16	55·408	55·44	54·99
Hydrogen . .	6·94	7·17	7·238	6·55	6·87
Nitrogen . .	16·02	15·86	15·593	16·65	15·66
Oxygen . .	21·34	21·81	21·761	21·36	22·48

These analyses may be represented by the formula $C_{144}H_{122}N_{14}O_{24}$, and consequently protein may be regarded as albumen in which two equivalents of sulphur are replaced by oxygen.

When protein, or the substances which yield it, are boiled in a concentrated solution of potash as long as ammonia is evolved, and the solution is afterwards neutralised by sulphuric acid, evaporated to dryness, and the residue treated with boiling alcohol, three products of the decomposition are dissolved, one of which, *erythroprotide*, separates in oily drops as the solution cools; *leucin* is deposited in small crystalline scales by spontaneous evaporation; whilst the mother water contains *protide* and formiate of ammonia in solution.

Binoxide, or *oxyprotein*, and tritoxide of protein are produced by the long continued action of boiling water upon fibrin in contact with air. They are the chief ingredients of the buffy coat of the blood in a state of inflammation, being produced at the expense of the fibrin.

PROTEST. [Bill of Exchange; Notary; Lords, House of.]

PROTESTANT, a general term comprehending all those who, professing Christianity, yet are not in the communion of the general church or confederacy of Christians of which the pope is the head and the city of Rome the centre or capital. There is great variety of opinion among persons thus separated, in points of faith, church order, and discipline, but this term covers and comprehends them all, leaving the varieties in opinion to be marks of specific differences only under the genus Protestant.

The term originated in Germany, and the occasion was this:—At the Diet at Spire, in 1526, decrees had been passed which were so far favourable to the progress of the Reformation that they went to forbid any peculiar exertions against it. The consequence was that the spirit of reformation gained strength, and spread itself more extensively in Germany. Then arose also commotions which were attributed to the reformed and to the spirit kindled by them. Both the pope and the emperor looked with increasing alarm on the aspect of affairs, and at another Diet, held at the same place in 1529, the emperor directed an imperial brief to the persons assembled, to the effect that he had forbidden all innovation, and proscribed the innovators in matters of religion, who had notwithstanding increased since the decrees of 1526, but that now, by virtue of the full powers inherent in him, he annulled those decrees as contrary to his intentions. The peremptory tone of these letters alarmed the persons present at the Diet; and particularly the elector of Saxony is reported to have said to his son, that no former emperor had used such language, and that he ought to be informed that their rights were more ancient than the elevation of his family.

This strong measure of the emperor had also the effect of uniting, at least on this point, the two great sections of German reformers, the Lutherans and the Sacramentarians, of whom Zuinglius was the head. However, the party opposed to the Reformation was the stronger, and the emperor's brief received the sanction of the Diet. Then it was that the reformers took the high ground of declaring that this was not a business of policy or temporal interests, with respect to which they were ready to submit to the will of the majority, but it affected the interests of conscience and futurity. On this and other grounds they founded a *protest*, which was delivered in on the 19th day of April, but refused by the Diet. A second protest, larger than the former, was presented on the succeeding day. The princes and the cities who favoured the Reformation joined in it, and thenceforth it became usual to call the reformers *Protestants*.

It is often found that a particular incident or occasion leads to the construction of a name for a religious party, which becomes extended, as in this instance, to parties who have no immediate connection with the particular incident, or interest in the question with which it is connected. The term Protestant, in fact, seems to have as much to do with the constitution of the Germanic confederacy as with the principles of the Reformation; and certainly, neither England nor Scotland had anything to do with the proceedings of the emperor or with the Diet of Spire. The Reformed Church might seem to designate the Church of England or the Church of Scotland more appropriately than the Protestant church. However, it must be owned, that few things are more difficult than to coin terms by which to designate a religious community which shall not be open to objection and cavil.

PROTRACTOR. Any instrument for laying down angles is so called, such as the graduated semicircle which is found in cases of instruments, the rectangular ruler with graduated edges, and various other more expensive contrivances. But the truth is that the easiest and safest protractor is a table of Chords, a scale of equal parts, and a pair of compasses: those who have not a sufficient table of chords should take the chord from a table of sines by the formula—

$$\text{chord of } x = \text{diameter} \times \text{sine of half } x.$$

Even the scale of chords laid down on the rulers, used in the usual manner, is a better protractor than the graduated semicircle, which is worthless, except for very rough work. A good table of chords carried to every minute under 180°, is, we believe, not yet published in this country.

PROVERB (from the Latin *proverbium*, that is, *pro-verbum*, in which respect the form of the word bears analogy to *præludium*, and other words of the kind), a by-word, which meaning is also conveyed by *adagium*, "adage," and the Greek *paroemia* (παροιμία). Of the many definitions which have been given of a proverb, the best appears to be the following by Synesius, a Christian writer of the early part of the 5th century, who quotes from a work of Aristotle, now lost: "A proverb is a remnant of the ancient philosophy preserved amidst very many destructions on account of its brevity and fitness for use." To collect and explain such portions of wisdom has engaged the attention of some of the most learned men. Aristotle, Theophrastus, Chrysippus, and others, according to Laertius, made collections of proverbs. With the works of Plutarch is printed ('Opera Moralia,' vol. v.) a collection of 131 proverbs, with explanations; and, though this collection has not been uniformly acknowledged as Plutarch's, there is good reason to believe it to be his genuine work. Zenobius or Zenodotus, a Sophist who lived at the beginning of the 2nd century, made an epitome of the proverbs of two older writers, Tarræus and Didymus, in number 552. Diogenianus lived about the same time as Zenobius, and made a collection of proverbs, amounting to 775. These two collections, together with 1400 proverbs out of Suidas, and an appendix of 353 from the Vatican Library, and a selection of proverbs in metre, were well edited by Andrew Schott, 4to, Antwerp, 1612. The adages of Erasmus, in number 4151, are too well known to require any description. They are presented in their most useful form in the Epitome of them published by the Elzivirs, 12mo, Amst., 1663. Many modern writers have published collections of proverbs from various languages. The name of our own countryman, John Ray, is familiar to all the lovers of natural history. In 1672 he published his collection of proverbs, which has been often reprinted. Modern languages contain a great number of proverbs, and it is remarkable how many can be traced to an ancient origin, and how many are the common property of nations civilised and barbarous, so as to seem almost universal. Again, the proverbs peculiar to a nation or country never fail to mark distinctly the character and condition of the people. There is a valuable collection of English proverbs, with lengthened explanations, by Ray, by Oswald Dykes, and by H. G. Bohn, which also contains a selection of foreign proverbs.

PROVERBS OF SOLOMON, one of the canonical books of the Old Testament. The Hebrew מָשָׁל, translated *proverb*, denotes a similitude, and is rendered in the Septuagint by παροιμία, but oftener by παραβολή.

This book has always been ascribed to Solomon, though he was not the author of all its contents. The thirtieth chapter is entitled "The words of Agur the son of Jakeh," and the thirty-first chapter, "The words of King Lemuel;" and it is not improbable that many of the proverbs in the preceding part of the book were in current use long before the time of Solomon. The portion from the tenth chapter to the end of the twenty-fourth, comprises what may more strictly be called the 'Proverbs of Solomon.' The first nine chapters form a kind of introduction, and the remaining chapters after the twenty-fourth may be regarded as an appendix to the whole.

The Book of Proverbs is classed by Bishop Lowth among the didactic poems of the Hebrews ('De Sacra Poesi Hebr.,' Præl. xxiv.) The attentive reader of the original will discover the utmost exactness in the choice and arrangement of words, and will be able with ease to carry out the principles laid down by Lowth relating to the structure of Hebrew metre.

The Proverbs of Solomon are all pre-eminently adapted to teach the lessons of prudence, morality, and religion. They are a precious treasury, from which men may be supplied with the best rules for the conduct of life. (Patrick *On the Proverbs of Solomon*; Horne's *Introduction*.)

PROVIDENCE is the superintending care with which God watches over his whole creation, and especially over the human race. It has been generally held, as a direct consequence of the existence of a God who has created all things, that he must also uphold by his constant care everything which he has created. This doctrine however has been denied by the ancient Epicureans and the modern Theists, who, while admitting that God created the universe, and impressed upon it the laws by which it is governed, have contended, that having done this, he has left those laws to work out their own results without his further interference. The arguments for a superintending providence are derived from the order of the material universe, which we find to be governed by ever-active principles, of which no other explanation can be given than that they are the results of the power of God in continued exercise; from the events which are recorded in history, and which are daily occurring, such as the punishment of guilty nations and individuals, the exaltation of the virtuous, the adaptation of great men to the exigencies of their times, not to mention other circumstances in the history of individuals, which might be considered of a more doubtful character; and lastly, from the unequivocal statements of Scripture. The whole sacred narrative is evidently intended to show how God's providence wrought for the accomplishment of his own designs. Moreover, individuals are mentioned, such as Pharaoh, Nebuchadnezzar, and Cyrus, whom God raised up expressly in order to use them as instruments to effect certain objects. Two books of the Old Testament, those of Job and Esther (we might perhaps add those of Ruth, Jonah, and even others), appear to have been written for the very purpose of confirming our faith in the providence of God; and numerous passages might be quoted which teach the care of God over the whole universe (Col. i. 17; Heb. i. 3; Rev. iv. 11), over all men, whether good or wicked (Job xxv. 3; Matt. v. 45; Acts xvii. 28; James i. 17), and especially over his own people (Matt. v. 25-34, &c.).

The providence of God has been divided by theologians into *immediate*, or that which he exerts without the intervention of second causes, and *mediate*, where ordinary means are employed; into *ordinary*, which relates to occurrences in the common course of nature, and *extraordinary*, where that course is departed from, as in the case of miracles; into *common*, of which the whole world is the object, and *special*, which regards the church; and into *universal*, which describes the care of God for his whole creation, and *particular*, which is exercised for the benefit of individuals.

PROVINCIA may be defined generally to be a conquered country, beyond the limits of Italy, which was subject to the Roman state. In contemplating the history of Rome, the most instructive part of it, next to a study of the internal organisation of the state, is the system of provincial government by which the language and laws of Rome were established on a foreign soil. The effects of this system are permanently embodied in the political system of every European state. In order to exhibit a complete view of Roman provincial government it would be necessary to write the history of Rome, but the following outline may be useful.

The geographical sense of the word Provincia was not the original meaning; originally the term expressed the Imperium, which was granted to a consul or prætor beyond the limits of the city. The precise meaning of the word is not certain, and the common etymology is perhaps doubtful; its primary sense however certainly was a power as above explained. In the time of Cicero provincia had undoubtedly obtained the meaning given at the head of this article; and in the latter part of the Republic, the Roman state consisted of two distinctly organised parts, Italy and the Provinces. This distinction, though with considerable modifications, continued under the Empire.

With the extension of the Roman conquests beyond Italy, commenced the system of provincial governments. The oldest provinces were Sicily (B.C. 243) and Sardinia (B.C. 237). Upon the conquest of a country, the commander of the army either gave the conquered country a general organisation, subject to the approval of the senate; or the country was organised according to the instructions of the senate, by the commander and a body of commissioners chosen from the senate, and appointed by it. This original organisation often made very important changes in the existing political forms, but still the conquered people retained their national existence, and were not in all senses incorporated into the Roman state. Originally prætors were appointed to govern the provinces [PRÆTOR]; but subsequently the prætors received a province after the expiration of their year of office at Rome, and were then called proprætores; and towards the close of the Republic the consuls in like manner received provinces, which were hence called consulares, and they were styled proconsules. The division of the provinces was made by lot, and sometimes by agreement among the persons entitled to hold them. By a law of C. Gracchus (Sempronia lex), the provinces of the consuls were annually determined before the election of the consuls, for the purpose of preventing all disputes.

By a senatus consultum of the year 55 B.C., it was enacted that prætors and proconsuls should not have the government of a province till five years after the expiration of their prætorship or consulship. The term for which a province was originally held was one year; but the time was often enlarged. The authority of the governor of a province commenced as soon as he left Rome. His functions in the province were both military and civil; he possessed the Imperium, but he was not called a magistratus. In the later Roman writers the common name for governor is præses (Gaius, i. 6), and sometimes the term proconsul seems to be used generally for the governor of a province. The governor was assisted in the discharge of his duties by a quæstor, who looked after the revenue; and by legati, who assisted in the administration, and were generally appointed by the senate, but sometimes by the governor with the permission of the senate. He had also a numerous train of friends and companions, sometimes called contubernales; and also a regular body of clerks, interpreters, and other servants, who formed a prætorian cohort, a name which was also given, and with more propriety, to the soldiers who formed the governor's body-guard. On a new governor arriving in his province, the former governor was required to leave within thirty days.

The province was treated as a conquered country, though the towns retained somewhat of their municipal freedom, but the constitution of many of them at least was re-fashioned upon the model of Rome, though in this respect there were probably considerable varieties. Under the emperors the political organisation of the whole empire became more uniform. The towns had the management of their revenue, and the right of coining; but only towns of the highest class could coin silver. They had a senate like those in the Italian towns, but no magistrates with corresponding powers. The religion of the people was not interfered with.

In some cases part of the land of conquered foreign countries was seized by the Roman state, and let by the censors; or the forfeited land was restored, subject to the payment of a rent. All provincial land differed in some essential particulars from Italian land: it could not be the subject of quiritarian ownership, that is, it had not the privileges of Italian land, and it was capable of being transferred without the forms required in the case of Italian land. There was private property in provincial lands, but the ultimate ownership, in the Imperial period at least, was considered to be in the Cæsar or in the Roman state (populus Romanus). (Gaius, ii. 7.) All provincial lands paid taxes (vectigalia et tributa). But certain provincial towns received as a special favour the Jus Italicum, the legal effect of which was to give the land included within the limits of such town all the qualities of Italian land, and consequently freedom from taxation. Such towns also received, as a part of the Jus Italicum, a free constitution like that of the Italian towns, and with it the various magistrates, decemviri, quinquennales (censors), ædiles; and also jurisdictio, or the power of holding courts of justice. Various towns which enjoyed this privilege are enumerated, in Spain, Illyria, Gaul, and elsewhere. The origin of this privilege is assigned by some writers to the Imperial period; but perhaps it commenced earlier. In all the provinces the regular jurisdiction was in the hands of the Roman governor, who exercised it by himself and his quæstor and legati; and for this purpose he made circuits in his province. In reference to this part of his duties, the governor is sometimes called Judex Ordinarius under the later emperors. These circuits, sometimes called conventus, formed what we may call the divisions of a province for judicial purposes. Thus Pliny (iii. 3) says that Hispania Citerior was divided into seven conventus, which he enumerates. The towns which had the Jus Italicum were not comprised in the conventus; they had their magistrates, in the Italian sense of the term, who had jurisdictio; but there was an appeal to the governor. At these conventus there were present a great number of Roman citizens, who were engaged in commerce in the province, or who were publicani, farmers of the revenues. These conventus, which are frequently mentioned by the Roman writers, were not accidental assemblages of persons, but meetings at stated times and places appointed by the governor, and principally for the purpose of judicial decision on matters in dispute, both between Roman citizens, and Roman citizens and the provincials. The judices were chosen, after the Roman fashion, from the persons who attended the conventus, or circuit courts. It appears that the fundamental laws of a province were not interfered with, for, as we have seen, the soil retained its former legal character, and was not invested with that of Italic soil, and the personal status or condition of Roman citizens was not communicated to the provincials merely as such. Some of the provinces, as Sicily, obtained the Latinitas [LATINUM JUS] from Julius Cæsar, and the Civitas, or complete Roman citizenship, was given to the Sicilians after his death (Cic., 'Ad Att.,' xiv. 12); but this was not the general rule. By means of the edict, which the prætor published on entering upon his duties, and which was often framed upon the prætorian edict at Rome [PRÆTOR], many important changes must have been gradually introduced into the legal system of the provinces, and particularly with reference to matters of contract and forms of procedure, in which there could be no ground for the same distinction that was maintained between provincial and Italic land, and which necessarily influenced the rights of landholders and the forms of action. The prætor had complete jurisdiction in criminal as well as civil matters, and both over provincials and Roman citizens; but a Roman citizen could appeal to Rome in a criminal matter.

A province consisted of a variety of parts. Some towns included in it had from the commencement an alliance with Rome, and were in all respects free. Others, which had been subdued, were declared free, and were not under the immediate jurisdiction of the prætor. The provinces also contained numerous colonies, and both colonies of Roman citizens and colonies of the class called Latinæ. [LATINUM JUS.] Thus towards the close of the republican period a province contained, besides those parts of it which were subject to the complete jurisdiction of the governor, allied towns, free towns, Roman colonies, and Latin colonies. According to this view, the provincia properly comprised those parts and towns which were subject to taxation and to the prætor's immediate jurisdiction. Some writers assert that the Roman and Latin colonies which were sent from Italy into the provinces were in all respects like such colonies in Italy, and that these colonies had quiritarian ownership of the soil, and consequently freedom from taxes. But there is some difficulty about this part of the subject. The privileges called Latinitas, or Latium, were often given to particular towns, one effect of which was to release them from the immediate jurisdiction at least of the Roman governor, and to give them a jurisdictio, or power of holding courts: citizens who filled certain offices (magistratus in such towns), thereby obtained the Roman citizenship. (Strabo, p. 186, speaking of Nimes.)

The taxes which were raised in the provinces varied in the different countries, but generally consisted in a capitation tax and a property tax: the latter was sometimes paid in money and sometimes in kind. The state did not collect the taxes, but they were sold or farmed: thus, after the Sempronia lex, those of the provinces of Asia were sold by the censors at Rome, and those of Sicily, with some exceptions, were sold in the respective districts of the country, according to a practice established by Hiero. There was also money paid for the use of the open pasture lands, which the Roman state appropriated to itself. The tolls and port duties, as well as the pasture-land tax (scriptura) were farmed by the publicani. [PUBLICANI.] Besides these and other regular sources of revenue, the province was subjected to many exactions, some of which had a kind of legalised form, and others were merely gifts made to satisfy the demands of the governor, or to secure his favour.

The governor had to give an account of his administration from his own books and those of his quæstor. Originally he gave in this account at Rome; but after the Julian law (B.C. 61), he was required to deposit two copies in the two principal towns of his province, and to send one to the Ærarium at Rome. If the province had ground of complaint against him for mal-administration (repetundæ, peculatus), which was no uncommon thing, application was made to the Roman senate; and the great Romans, who were the patrons and friends of the cities which made the complaint, were also applied to for their aid and interest. If he had betrayed the interests of the Roman state, he was guilty of the offence of majestas. A regular mode of inquiry and trial (quæstio) were adopted for such occasions. Yet little was done without bribing the powerful men at Rome; and the chance of redress against a governor who had even grossly misconducted himself was very small: it was more frequently obtained through the influence of the powerful Romans, stimulated by motives of private hostility to the accused, than through the justice of the case.

With Augustus commenced a new period. He took under his own care the more important provinces, and those which required a large military force; the rest he left to the care of the senate and the Roman people. This arrangement continued, with some modifications, to the 3rd century. Of the provinces of the senate, two were yearly given to consular men, and the rest to those who had been prætors: these governors were all called proconsuls, and they were assisted by legates. They had the jurisdictio both of the prætor urbanus and peregrinus. Quæstors were also sent with them to their provinces: the quæstors had the same jurisdictio that the ædiles had at Rome. It seems however that the power of the proconsuls in their provinces was considerably diminished. The emperor considered himself as the proconsul of his own provinces; and he governed them, though residing in Rome, by his representatives called legati Cæsaris, who had prætorian power. They were selected from those who had held the office of prætor and consul, or were senators of inferior rank. The Imperial governor of Egypt was called præfectus, and he was always an eques. They held their office so long as the emperor pleased, and received all their powers directly from him. These governors of the emperor's provinces were called præsides and correctores in the later periods, though the name præses was applied under the emperors to a governor either of a senatorial or an Imperial province. They had also legati under them; but in the place of quæstors there was a procurator Cæsaris, who was an eques or a freedman of the Cæsar; he looked after the taxes and other dues of the emperor, paid the troops, and attended generally to the business of the fiscus. After the time of Claudius, the procurator had jurisdiction in matters that concerned the fiscus. There were also procuratores Cæsaris appointed by the emperor in the senatorian provinces, who collected certain dues, even in those provinces, for the fiscus, independent of what was the due of the ærarium, or public treasury. Sometimes a small province, or a part of a larger one, was governed by a procurator Cæsaris, with the full power of a præses; this was the case with Judæa, which was a part of Syria, and governed by a procurator who was under the præses of Syria. The general constitution of the provinces remained the same, though as before observed, a greater uniformity in administration was gradually introduced, and from the time of Hadrian the Imperial rescripts and the writings of the Roman jurists contributed to form a body of common law for the whole empire. The taxes continued as before, and were partly paid in money, and partly in kind; but the object of the Romans was always to have them paid in money. The basis of the taxation was a general census of persons and property, which Augustus introduced, and which was taken from time to time. Certain taxes, as tolls and duties, were let, as before, to the publicani. The towns, at least under the early emperors, seem to have retained their privileges; though some modifications were very early introduced; for instance, Augustus indirectly deprived the citizens of the colonies of their suffrage at Rome, a measure which seems to have led the way to other changes. Numerous colonies, chiefly if not exclusively of the class called military, were also established by the emperors in the provinces; and it is to this period that some writers refer the gift of the Jus Italicum to provincial cities.

The inhabitants of the provinces were now divided into three classes as to political rights, Roman citizens, Latini, and Peregrini. The Roman citizens were either Italians resident in the provinces; or members of Municipia and colonies which had the Roman citizenship; or those who had individually obtained this right. The two latter classes had all the privileges of Italians, except with some restrictions as to attaining the senatorian dignity; but many of them obtained the rank of equites. The Latini had not the connubium only and the commercium, but they could obtain the civitas in several ways. The Peregrini had neither the connubium nor commercium; in fact, they had none of those rights which characterised a Roman citizen; but yet they served in the army. By a constitution of Antoninus Caracalla (A.D. 211-17), the citizenship was given to all persons within the Roman empire, and accordingly the distinction of Civis, Latini, and Peregrini ceased, and the two latter classes henceforward only existed among manumitted slaves.

The administration of the provinces gradually came more under the power of the emperor, and particularly as to matters which required a legal decision; under the Christian emperors, though governors and other officers of provinces were appointed, the forms of the old Roman provincia were almost entirely superseded.

(Savigny, *Geschichte des Römischen Rechts im Mittelalter*, vol. i.; and Walter, *Geschichte des Römischen Rechts, &c.*, Bonn, 1840, afford abundant references to original authorities. Incidental information will also be found in the following essays:—'Das Ackergesetz des Sp. Thorius,' *Zeitschrift*, x.; 'Ueber den Inhalt der Lex Rubria de Gallia Cisalpina,' *Ibid.*, x.; 'Ueber das Jus Italicum,' *Ibid.*, vol. v.)

PROVINCIALISM. The difference between the languages of a family and the dialects of a language is only a difference of degree. For example, the Sanscrit, Persian, Teutonic, Greek and Latin, Slavonic, and Celtic, are languages of the Indo-Teutonic family [LANGUAGE]; and the Doric, Ionic, and Æolic are dialects of the Greek language. Although the dialects of a language may present considerable differences both in the roots and forms of their words, the differences are less considerable than those which obtain between languages of the same family. Thus a historian tracing the origin of the Romance languages might doubt whether he ought to consider them as altered dialects of the Latin language, or as cognate languages of the same family. If the Italian, Spanish, and French languages were considered as modern Latin dialects, their various dialects (such as the Sicilian, Venetian, Milanese, Walloon, Valentian, &c.) would be regarded as mere varieties, analogous to the varieties of the Doric dialect as spoken by the different states of the Doric race. (Müller's 'Dorians,' app. v.)

Every language which is spoken by a large population over a wide extent of country, contains several dialects. The number and variety of these is in some cases very great; and considering the importance of this fact as bearing on the origin and history of languages, it has not been sufficiently observed by philologists.

The cause of a want of attention to the multiplicity of dialects in a language is to be found in the ascendency which one dialect of a language always acquires over the others, and the obscurity and neglect to which the latter are consequently consigned. Whenever a country reaches a sufficient height of civilisation to admire and produce literary works, some one of the various dialects of its language is selected by the poets and other native writers, and is cultivated by them. In general, this choice is determined not by any quality of the dialect itself, such as its superior harmony or energy, but by some external circumstance, such as its prevalence near the birth-place or home of the writer, or near the king's court and seat of the government. When a dialect, by any of the means above described, has been distinguished from and raised above the others, it is adopted for all the native literary compositions, both in poetry and in prose. Hence it is still further cultivated, and is moreover thereby rendered more susceptible of ulterior cultivation and refinement. It becomes the general language of the government, of education, of literature, and of polished society; new words are introduced into it from other languages, ancient or modern; and it is learned by foreigners.

The rise and progress of one dialect, according to the general description just given, may be observed to have taken place in every civilised country. In Greece, on account of the multiplicity of independent states into which the nation was divided, each dialect of the language received a separate cultivation. The early historians and philosophers wrote in the Ionic dialect, and lyric poetry was composed in the Doric and Æolic dialects. But after the Persian war, and the great predominance of the Athenians, both in political power and in literature, the Attic dialect obtained the ascendant in Greece and became the common literary language. (Müller's 'History of Greek Literature,' c. 20, § 1, 2.) In like manner, the Tuscan dialect, chiefly on account of the pre-eminence of the Tuscan writers, became the literary language of Italy, and threw into the shade the Sicilian dialect, in which the first essays of Italian poetry were made. But notwithstanding the predominance of the literary Tuscan in Italy, both as the literary language and as a means of communication between inhabitants of different parts of Italy, yet every Italian city or territory has its own dialect, which is habitually spoken, not only by the lower and middle classes, but also by the upper classes when persons from other parts of Italy or strangers are not present. In France, the dialect of the *langue d'oil*, spoken in and about the seat of government, has not only thrown into the shade the other dialects of that language, spoken in the northern portion of the kingdom, and reduced them to the condition of mere patois, but it has also superseded the *langue d'oc*, the language of the south, which had been raised to considerable literary importance by the poems of the Troubadours. The Castilian dialect has obtained a similar ascendency in Spain through the influence of the Castilian writers; and the high German of Saxony has become the literary language of Germany mainly through the influence of Luther's translation of the Bible; although the Suabian dialect received a literary cultivation in the lays of the Minnesingers before any other of the German dialects. The classical English is mainly formed upon the dialect spoken in Middlesex, and the counties in the neighbourhood of London. Its forms differ materially from those of the dialects spoken in the more distant counties, as Devonshire, Somersetshire, Cheshire, Lancashire, and Yorkshire; and still more from those of the dialect of the English which is spoken in the lowlands of Scotland, and in the border counties of England. The latter dialect has received considerable literary cultivation not only from early writers, such as Buchanan, Barbour, and others, but also from Burns, Walter Scott, and their imitators, who have used it with great skill and success for ballad-poetry and tales of fiction; nor have the other dialects been altogether neglected, as several works, particularly poetry, have been produced in them, among which we may mention Miss Blamire and R. Anderson in that of the Borders; for the south of England the very superior works of Mr. Barnes, 'Poems of Rural Life, in the Dorset Dialect, with a Dissertation and Glossary,' 12mo, 1847, and 'Hwomely Rhymes,' 12mo, 1859; and the poems of Edward Capern, the Bideford postman, for the west.

The peculiar dialect of the English which has been formed in the New England States of the American Union is noticed under AMERICANISM.

By a provincial word is meant a word which is not received in the literary language of the time, but which is current among the inhabitants of some district; and provincial words may be divided into the following classes:—

1. Words formerly current in the literary dialect of the language, but which have ceased to be so, and are current only as provincialisms. For example, the word *cantle*, meaning a piece or fragment, and *shard*, meaning cowdung, are used provincially in parts of England, though obsolete in the literary language. They were however literary words in the time of Shakspere, and are used by him in 1 Hen. IV., act iii., and Macbeth, act iii.

Sometimes an ancient classical word, though current provincially in ordinary discourse, is used as a literary word only in poetry or as a technical term. Thus the old words *craven* for coward, and *dank* for damp, which are still used familiarly in the provincial language of some districts, could only be employed as literary words in poetry or in poetical prose; and the old word *soller*, meaning an upper floor, which is current as a provincialism in many parts of the country, is only recognised by the literary language as a legal term, being thus used in the general words of a conveyance ("cellars, sollers," &c.)

2. Words which are not known to have ever been received in the literary language of the country. Many words of this class will occur to any person who consults a provincial glossary of any language. In some cases the word differs widely from any word which occurs either in the modern literary language or in old writers; more frequently however the difference consists mainly in the form. The Scotch dialect presents obvious examples of all these varieties. Sometimes a provincial word is not a dialectical variety of form, but is a corruption arising from ignorance, as *atomy* for *anatomy*, *rusty* for *restive*.

Provincial dialects are chiefly preserved among the humbler and illiterate classes; educated persons generally speak the literary language of the country. Moreover they are chiefly preserved in rural districts; and thus many of the provincial words relate to agricultural subjects. (Preface to Boucher's 'Glossary,' p. xliv.) In Fielding's time, country gentlemen in England often spoke the provincial dialect of their county, as may be seen by Squire Western's language in 'Tom Jones.'

Provincialisms, being either ancient classical words, actually obsolete in the literary language, or diverging words or forms in a parallel dialect, are genuine remains of the ancient language of the country. In this respect they differ materially from the following classes of words:—1. Low, vulgar, or obscene words, which are of universal or general currency, and are not confined to any particular locality. (Grose's 'Dictionary of the Vulgar Tongue,' and the 'Dictionnaire du Bas Langage.') 2. Slang or cant expressions, used by gypsies and thieves for the purpose of concealing the subject of their conversation in the presence of persons who are not their accomplices (called *gergo* by the Italians, *ergot* in French, and *germania* in Spanish). A slang or cant language is often formed among classes of persons following any peculiar pursuit; thus there is a slang of the prize-ring and the stable in this country, and there is said to be a slang among bull-fighters in Spain. 3. Technical words, such as the peculiar language of sailors or miners. 4. Neologisms, such as the words *talented*, *jeopardise*, in English.

Collections of provincial words are important in a philological point of view, as throwing light on the formation, structure, and analogies of languages; they are also important in a historical point of view, as illustrating the changes in the language of a country.

The glossaries of provincial words which have been published in foreign countries are very numerous, though in general they have been made with little philological skill or knowledge, and are meagre in the explanations and illustrations of the meanings of the words. For the English language the most recent and comprehensive general works are those of Mr. J. O. Halliwell, 'Dict. of Archaic and Provincial Words,' 2 vols. 8vo, 1860; and Wright's 'Dictionary of Provincial and Obsolete English,' 1857; and there are glossaries with specimens in prose and verse of the dialects of Norfolk, Suffolk, Sussex, Devonshire (by Mrs. Palmer, the sister of Sir Joshua Reynolds), Somersetshire, Cornwall, Herefordshire, Cheshire, Lancashire, Yorkshire, Cumberland, Westmoreland, and Northumberland; to which may be added Jamieson's 'Scottish Dictionary;' and that of the Northamptonshire dialect, a most comprehensive work, by Miss Baker.

PROVISIONS; PROVISORS. [Præmunire.]

PROVOST, a term having its origin apparently in the Latin *præpositus*, which denotes the chief of any society, body, or community. In France the corresponding word *prévôt* approaches nearer the original form. In that country it is applied to the persons who discharge the functions of many different offices, but in England it is rarely used: instances occur in the heads of certain colleges, as Eton, King's College (Cambridge), &c. But in Scotland it is used to designate the chief officer in cities, as the provost of Edinburgh or of Glasgow, where in England the same officer is called the mayor.

PROVOST-MARSHAL, a term adopted from the French, who called an officer with similar functions the prévôt des maréchaux de France. The English provost-marshal is attached to the army, his duty being to attend to offences committed against military discipline, to seize and secure deserters and other criminals, to restrain the soldiery from pilfering and rapine, to take measures for bringing offenders to punishment, and to see to the execution of the sentences passed upon them.

PROXY. [Lords, House of.]

PRURIGO is a disease of the skin characterised by an eruption of small pimples and a most intense burning sensation of itching. The pimples are usually but slightly if at all red, and the skin between them has its natural colour. They are generally seated about the shoulders, back, and neck, but often also on the limbs, and in severe cases even on the face and over a great part of the body. Their course is always very slow, and they are not infectious.

There are three principal varieties of Prurigo, namely, *P. mitis*, *P. formicans*, and *P. senilis*; and besides these, some others are distinguished by the names of the parts which are in each exclusively or chiefly affected.

The *Prurigo mitis* is the mildest form of the disease. The pimples are very small, and so pale that they can scarcely be discerned, till, by the scratching, which is almost unavoidably resorted to in order to relieve the intolerable itching, their tops are torn off, and become covered by little black scabs of dried blood.

In *P. formicans* all the symptoms of the disease are more severe, and the itching by which they are accompanied is united with a painful burning sensation in the skin, as if, patients say, hot needles were constantly piercing it. Both this and the preceding form of Prurigo may disappear with a slight desquamation in a few weeks, but more commonly a succession of eruptions follow one another, and the disease is prolonged for months or even years. Both of them occur in persons of all ranks and ages, but they are most common in the young and in the old, and among those who enjoy fewest of the comforts of life. They are not attended by any important constitutional disorder.

Prurigo senilis, which is by far the worst form of the disease, occurs almost exclusively in enfeebled children and old people. It usually lasts four years, producing all the time almost intolerable suffering by the intense itching that attends it, and which scarcely admits of relief by any known means. The pimples are usually very numerous, and often hard and prominent; the skin between them is also often thickened and indurated, other eruptions break out upon it, and if cleanliness be not carefully observed, it becomes infested with swarms of lice.

The treatment of the first two forms of Prurigo must consist of a mild antiphlogistic regimen, tepid baths, and the use of alkalies both externally and internally. Stimulants of all kinds greatly increase the pain and itching, but they may sometimes be relieved by the application of ointments or lotions containing small quantities of opium, or prussic acid, or cyanuret of potassium. In the *Prurigo senilis* the regimen must be more nutritious, and tonic medicines are useful; but in this form, as well as in the others, stimulants must be avoided. If the skin is infested with pediculi, the most effectual mode of destroying them is fumigation with the vapour of cinnabar. In this form also sulphur-baths are among the few means that will produce any relief. The alkaline lotions, which may be used in all cases, may be composed of one or two drachms of carbonate of potash to the pint of water, or of from one to three drachms of sulphuret of potash to the same quantity of water, the strength being determined by the irritability of the skin, and being always made less than sufficient to excite any heat or redness in it.

PRUSSIC ACID. [Cyanogen, *Hydrocyanic Acid.*]

PRUSSIC ACID, *Medical Properties of.* This is termed also, from its chemical composition, hydrocyanic acid. Its medical employment, and its connection with medical jurisprudence, from the frequent use of it in cases of death, accidental or intentional, merit the most attentive consideration. But these are unsuited for popular discussion. A few important rules and cautions can alone be furnished here.

Much variation in strength exists in the acid (that is, the dilute acid, for the anhydrous is always of definite strength), owing to different methods of preparation. Thus not only does a difference of strength exist in the acid as it is enjoined to be prepared by the Edinburgh and London colleges, but even in England two preparations are commonly met with, that enjoined by the London Pharmacopœia, which contains 2 per cent. of real acid, and that which has been long known as Scheele's, containing 4 per cent. The substitution of the one for the other in preparing a prescription might lead to serious if not fatal consequences. This anomaly will be removed by the General Pharmacopœia now preparing for use through all Great Britain and Ireland. A still greater difference exists in the strength of the preparations met with in different countries of the Continent. No one in travelling should ever prescribe prussic acid, unless he has previously ascertained what preparation will be employed in compounding the prescription.

As it undergoes decomposition by time, especially if exposed to the light, and is readily volatilised at a high temperature, it should be kept in the dark, and in a cool place. As it is specifically lighter than water, it rises to the surface in watery fluids. The fluid in which it is kept should be well shaken before pouring it out. When employed externally as a lotion, in which case it is used in larger doses than when meant for internal employment, great care should be observed to distinguish it, lest it should be accidentally taken internally. This is attempted to be accomplished by using phials of a peculiar shape and colour. Even its external employment demands great care, for when the cuticle is abraded or cracked, it is readily absorbed, and may prove fatal. The cuticle, even when in a state of integrity, is not proof against the vapour of prussic acid. All bottles containing the acid should be kept well corked, as the vapour is the most potent form which can influence the human frame. It is important to know that this acid is liable to be formed in some medical mixtures spontaneously, without the assistance of heat or distillation. Thus it has been formed in a mixture of carbonate of potash with tincture of hyoscyamus, doubtless by the decomposition of the hyoscyamid furnishing nitrogen (see 'Journ. Pharm. Soc.,' vol. xiii. p. 632).

When first introduced into medical practice, high expectations were formed of the utility of prussic acid. Subsequent experience has moderated these expectations; but there is no doubt that it might be found useful in many instances where it is not employed, the dread of accidents deterring many medical men from using it. Such hesitation displayed by those who know its properties should furnish a salutary caution to all persons against employing it on their own responsibility. The diseases in which it has been most recommended are—affections of the lungs, whether acute inflammation, after the active stage is passed, or those of irritation. Among the former, hooping-cough is unquestionably benefited by it. But here great caution is necessary. Its premature employment, by checking the cough, induces inflammation, often of a very alarming kind. The dose should at first be very small, and most slowly increased. In some works, even emanating from medical men, large doses are most culpably ordered. More relief is obtained in consumption from Conium than from this acid. Some affections of the stomach receive signal relief; others derive not the least benefit from it. The explanation of this appears to be that in the former the causes of the disorder, as well as its seat, are in the stomach itself; while in the latter the pain is felt chiefly in the stomach, but the cause is in the spinal chord. Treatment directed to the spine will in general quickly and often permanently relieve the sufferer. (Teale's 'Treatise on Neuralgic Diseases.') Cutaneous diseases are alleviated by lotions and ointments containing hydrocyanic acid. But the cautions above given must be carefully observed during their employment.

The most useful hints which can be here given relate to the treatment of poisoning by prussic acid. So soon as it is ascertained or suspected that any one has taken an over or poisonous dose, cold water should be dashed over the head and back. The vapour of ammonia (common smelling salts) or of chlorine should be applied to the nostrils; or very dilute liquor ammoniæ may be thrown into the stomach. While these things are doing, other persons may prepare a weak solution of carbonate of potash (common pearlashes will answer); and some sulphate of iron (copperas) is to be dissolved in a large quantity of water. Some of the solution of the carbonate of potash is to be given to the patient, followed immediately by some of the solution of copperas. Phials containing these two solutions might be kept ready prepared in chemists' shops, so as to be at hand instantly. This if done promptly, will save the patient. Artificial respiration, if speedily resorted to, is useful, as is likewise bleeding from the jugular vein. Prussic acid (or its elements, which easily act on each other so as to form this compound,) exists in the leaves of the *Cerasus lauro-cerasus*, or Cherry-laurel, the mere bruising of which developes the characteristic odour and effects. This shrub is unfortunately often confounded with the true Bay, or Cæsar's Laurel, by cooks and confectioners, who use these leaves, (the amount of oil, from difference in the amount of the elements, varies at different periods of the year), to flavour dishes and cheese-cakes, with often fatal effects. Bitter almonds develope prussic acid.

PRY'TANIS (*Πρύτανις*), the name of the chief magistrate in many of the Grecian states. We read of this office in Corinth, Corcyra, Miletus, Tenedos, Pergamos, Cos, Rhodes, &c. (Wachsmuth, 'Hellen. Alterth.' i., p. 194.)

At Athens, the name of Prytanes (*πρυτάνεις*) was given to the members of the senate of five hundred, who acted as presidents of the senate and of the assemblies of the people. The senate of five hundred was divided into ten sections of fifty each, who were chosen respectively from the ten tribes into which the Athenian people was divided. Each tribe presided in turn during 35 or 36 days, as the case might be, so as to complete the lunar year of 354 days (12 × 29½). Their period of office was called a prytany (*πρυτανεία*). As however fifty was too large a number to conduct business conveniently, every fifty was divided into five bodies of ten each, who presided for seven days over the rest, and were therefore called proëdri (προέδροι); and from these proëdri an ἐπιστάτης was chosen for one day to preside as chairman in the senate and the assembly of the people; during his day of office he was entrusted with the keys of the treasury and archive office, and with the state seal.

The prytanes had a building to hold their meetings in, where they were entertained at the public expense during their prytany. This building was called the Prytaneion (πρυτανεῖον), and was used for a variety of purposes. (Hermann, 'Political Antiquities of Greece,' § 127.)

PSALMODY, in its widest sense, signifies the Psalms of David set to music and sung. But from the early part of the 16th century the term has been applied only to metrical versions of the Psalms to which short grave airs are either set or adapted.

The practice of psalm-singing may be traced to a very remote date, but we need not refer to any period anterior to that of our Saviour. In St. Matthew's and St. Mark's gospels (xxvi. 30; xiv. 26), we find that, after the last supper, Christ and his disciples "Sung an hymn" ("*or psalm*," says the marginal note), previously to their going "out into the Mount of Olives." St. Paul exhorts the Ephesians (v. 19) to "sing psalms and spiritual songs;" and St. James (v. 13) recommends those who are "merry" to do the like. The corroborative passage in the letter of the younger Pliny to Trajan ('Ep.,' x. 97) stating that the Christians sang hymns to their Christ before daybreak, is well known. The bishops Flavianus and Diodorus ordained that the Psalms of David should be sung by the choir, in the manner of the antiphons. [ANTIPHONY.] Among the inferior orders of clergy in the church of Rome were the Psalmistæ, whose first institution appears to have been at the commencement of the 4th century. It is believed that this order was established for the purpose of encouraging and regulating the ancient psalmody; for, says Bingham, "from the first and apostolical age, singing was always a part of divine service, in which the whole body of the church joined." (i. 295, *et seq.*) The service of the ancient church usually began with psalmody, according to St. Jerome. (Hieron., 'Ep.,' 22, 'Ad Eustach.') It was also the exercise and recreation of the Eastern churches in their nocturnal vigils; and, indeed, at all times in the church, St. Augustine remarks, was psalmody used to fill up vacant intervals. (Aug., 'Ep.,' 119, 'Ad. Januar.')

By degrees the greater part of the psalm-tune was surrendered to a single voice, the congregation joining only at the close. This led to a more scientific and perhaps a more refined mode of singing, requiring superior knowledge; and thus, the body of the people becoming incapable of taking a share of the performance, the service was left in the hands of professed musicians. This was encouraged by the Church of Rome, during her long dominion, because it still farther divided the clergy and laity: but Huss, and afterwards Luther and Calvin, restored to the people their share in the divine service, furnishing them at the same time with the means of performing it in a manner agreeable to themselves, and conformably to what they conceived to be the true principles of public worship. With this view the Psalms were turned into metre, tunes were composed or adapted, and the practice of psalmody soon became a marked distinction of those who departed from the Church of Rome. Luther, however, was friendly to harmony, or music in parts; the severe Calvin, on the contrary, sternly refused to admit anything but simple unaccompanied melody. The design of the reformers was seconded by Clement Marot, who translated the first fifty Psalms into French verse. These, adapted to popular airs, became exceedingly fashionable, and the length to which the new amusement of singing sacred songs was carried by the monarch of France and his courtiers, is fully described by Bayle (in a note on Marot), and after him by Warton ('Hist. of Poet.,' sect. xlv.), as well as others. Theodore Beza, by his version of those Psalms which Marot left untouched, completed the hundred and fifty. Most of the melodies to these, as used by the first Calvinists, are commonly attributed to Claude Goudimel and Claude Le Jeune, distinguished French composers; but Bayle, on apparently good authority, ascribes them to one Guillaume Franc; while some think that they were chiefly German. It seems almost certain that a few owe their birth to the great reformer himself, of whose musical knowledge undoubted proofs remain; and it is equally clear, for the reason before mentioned, that the *harmonised* tunes of Goudimel and Le Jeune were not admitted into Calvin's places of worship, though probably their melodies were.

At nearly the time that Marot's translation of the Psalms appeared, Sternhold and Hopkins, with several coadjutors, produced an English version, to which were adapted many of the best German and French tunes; and Strype says, "it is certain that Sternhold composed several at first for his own solace. For he set and sung them to his own organ, which music King Edward VI. sometime hearing (for he was a gentleman of the Privy Chamber), was much delighted with them." ('Historical Memorials,' bk. i., chap. 11.) But if this versifier possessed as little musical as poetical taste, it is fortunate for him that his compositions do not remain to demonstrate that he was no less unskilful in one art than in the other. It is, however, to be presumed that there having been many very able musicians in the service of the youthful Edward, they contributed something in aid of Sternhold's design. But it is now generally supposed that for the majestic melody to which our 100th Psalm is adapted, we are indebted to the genius of Claude Le Jeune. This forms the *taille*, or tenor part, of his 134th Psalm, as printed in the Leyden edition of 1635; and it is necessary to remark that he, as well as others in his time, made a practice of giving the subject, or air, as a kind of *cantus firmus*, to the tenor voice.

The first complete collection of psalm tunes for four voices deserving notice was published in 1621, by Thomas Ravenscroft, Mus. Bac., to which Tallis, Morley, Dowland, and all the great masters of the day contributed; the name of John Milton, the father of the poet, also appears there, as the composer of *York* and *Norwich* tunes. The editor supplied many, some of which are still in use; and to his collection all the numerous works of the kind since printed have been much indebted. About the year 1671, John Playford, a good musician, and a most useful industrious editor, printed, in 8vo, 'The Whole Book of Psalms in three parts,' in which he has judiciously given the melody to the soprano voice, to which it naturally belongs, and it ever since has retained its place. A few of the tunes in that collection are supposed to have been composed by Playford himself, whom Sir John Hawkins considers as "the father of modern psalmody." Subsequently to the last edition of his work, valuable additions were made to the stock of genuine English psalmody, by Dr. Croft, Courteville, Carey, &c., and Handel is the reputed composer of the sweet music to the 104th Psalm, which still continues in our chimes, and as the dirge at the soldier's funeral. Dr. Miller, of Doncaster, effected a considerable improvement in psalmody by his 'Psalms of David for the use of Parish Churches,' in which the version of Tate and Brady was employed, and drove Sternhold and Hopkins from many of their strongest positions. The extraordinary success of that work, which made its way into the remotest parts of Great Britain, raised up a host of rivals and the number of publications and of new tunes has since increased beyond calculation. The popular works of all foreign composers have been made contributory to that love of novelty which carries its influence even into the temples of religion, and many organists have fancied themselves qualified and privileged to print a collection for the use of the church or chapel in which they officiate. Hence the music which had become almost a part of our Liturgy is falling into desuetude, and modern hymns—not always the most appropriate or the best in point of composition—threaten finally to banish the fine characteristic harmony of our ancient psalmody. (Bingham's 'Antiq.;' Bayle; Strype; Warton's 'Hist. of Poet.;' Mason's 'Essay;' Hawkins; Burney; Dr. Vincent 'On Psalmody.')

PSALMS (ψαλμοί, from ψάλλω, *to strike gently*, and so, to play on a stringed instrument) denote generally the poems which form one of the canonical books of the Old Testament. This book is called in Hebrew סֵפֶר תְּהִלִּים (*sepher tehillim*), 'the book of praises.' Except in thirty-four cases, the Psalms have titles, which, though they are no part of the original, are of great antiquity. Some designate the writer or the subject, or the occasion, and some are not to be understood.

The book of Psalms is often called the 'Psalms of David,' though many of them were not written by him. The authors of the Psalms named in the titles are Moses, David, Solomon, Asaph, Heman, Ethan, Jeduthun, and the sons of Korah. Between the earliest and latest of the Psalms, a period of about one thousand years seems to have intervened.

According to the Masorites, the Psalms are divided into five books, of which the first ends with Psalm xli., the second with Psalm lxxii., the third with Psalm lxxix., the fourth with Psalm cvi., and the fifth with Psalm cl. The first three books end with 'Amen and Amen;' the last two with 'Hallelujah.' This division existed in the time of Jerome, but how long before is uncertain. It is thought to have been made for the purpose of rendering the Psalms in this respect like the Pentateuch. The collecting of the Psalms into one book is generally attributed to Ezra.

The Psalms afford an exemplification of every variety of Hebrew metre, and they are pervaded by the highest poetic feeling. They were designed to be rehearsed in the worship of God with the aid of instrumental music. David appointed the singing of the Psalms by a company of persons, trained for this purpose, in the worship of the tabernacle. (1 Chron., vi. 31; xvi. 4-8.) This practice was continued by Solomon in his Temple (2 Chron., v. 11-13), and, after the interruption occasioned by the Captivity, it was renewed by Ezra. (Ezra, iii. 10, 11.) The New Testament furnishes evidence that Psalmody formed, in the time of Christ and his Apostles, a part of the worship of God, and the Christian church has in all ages followed the example. The book of Psalms obtained extraordinary attention among the early Christians. Theodoret, who wrote in the first half of the 5th century, says ('Preface to the Psalms') that while most men paid little or no attention to the rest of the Scriptures, they were so familiar with the Psalms, that in their houses, in the streets, and in the highways, they enjoyed profit and delight by the singing of these divine odes.

The canonical authority of the book of Psalms has never been disputed. There have been many works written as commentaries or explanations of the Psalms, and more than one translation. Indeed the version in the authorised translation of the Bible and that in the Prayer Book vary, though not much. Among the best works on the subject may be mentioned Tholuck, 'Uebersetzung und Auslegung der

Psalmen,' 1843; and Hengstenberg, 'Commentär über die Psalmen,' 1843-5.

PSALTERY, an ancient musical instrument of the harp kind, in use among the Jews, and supposed by Blanchinus to have been the נֵבֶל, *nebel* (whence *ναβλα* and *nablum*), mentioned in several of the Psalms. Whether this instrument was square or triangular, and played on by the finger, or struck by a plectrum, seems doubtful; the probability is that it took many forms, and was acted on both ways. Blanchinus makes it square, Luscinius triangular. According to Mersenne, and after him Kircher, the Psalterion, as they denominate this instrument, adopting the Greek term, was in shape a trapezium, and similar to that which is still in use under the name of dulcimer. [DULCIMER.]

PSEUDERYTHRIN. [LICHENS, COLOURING MATTERS OF.]

PSEUDO-ACETIC ACID. A name given to a peculiar acid strongly resembling acetic acid, said to be occasionally formed during the manufacture of tartaric acid.

PSEUDOMORPHINE. [OPIUM, ALKALOIDS OF.]

PSEUDORCIN. [ERYTHRIC ACID.]

PSEUDOSULPHOCYANOGEN. (Cy_3HS_6?) When a solution of sulphocyanide of potassium is treated with a current of chlorine, or by boiling dilute nitric acid, an orange-yellow coloured precipitate is obtained which seems to possess the above composition. It is insoluble in water, alcohol, and ether, but dissolves in concentrated sulphuric acid. When heated, it yields bisulphide of carbon, sulphur, and hydromellon:—

$$\underbrace{3Cy_3HS_6}_{\text{Pseudosulpho-cyanogen.}} = \underbrace{6CS_2}_{\text{Bisulphide of carbon.}} + 6S + \underbrace{3NHCy_2}_{\text{Hydromellon.}}$$

PSILOMELANE. One of the native forms of binoxide of manganese. [MANGANESE.]

PSORA. [ITCH.]

PSORI'ASIS is a disease of the skin distinguished by slightly raised red patches of various extent and form, and generally covered with whitish scales. Several varieties of the disease have received different names, according to the form and severity of the eruption in each, and many others, according to the part chiefly or alone affected. The former varieties are *Psoriasis guttata*, *P. diffusa*, *P. gyrata*, and *P. inveterata*; among the latter are *P. ophthalmica*, *P. palmaria*, &c.

Psoriasis guttata is a mild form of the disease, consisting of small red patches two or three lines in diameter covered with very fine white scales. It occurs in various extent on all parts of the body, but most rarely on the face. At first small red spots appear, and soon after present white scales at their centres; then the spots gradually enlarge and the scales increase in number, till the redness begins to fade at the centre, and as the scales fall off, the skin slowly assumes its natural colour. The eruption is attended by a moderate itching, and by very slight symptoms of general disorder.

P. diffusa is in every respect a more severe form of the disease. The spots are large and irregular, and often confluent, and covered with thick scaly incrustations. It appears most frequently on the limbs and around the joints, often covering the whole of a limb with one scaly or raw-looking patch, and sometimes occurring at once and with equal severity on several parts of the body. The skin beneath the scales is very tender and irritable; it often cracks and discharges a thin ichor, which concretes about the fissures, and is attended by considerable pain and irritation, and some constitutional disturbance. The eruption often breaks out successively in different parts of the body, so that it is common for the disease to be protracted for several months and even for years.

P. inveterata is only (as its name implies) a yet less curable form of the same disease. The skin has its whole texture thickened and hard, its surface is covered by a furfuraceous deposit, and in the neighbourhood of the joints it is often very deeply and painfully cracked. The preceding forms are commonly met with in those who are otherwise in pretty good health; but this rarely occurs, except in those whose constitutions are enfeebled by long disease or want.

P. gyrata is a slight but very rare variety, distinguished by the patches occurring in stripes of a singularly tortuous or serpentine form.

Of the local varieties of Psoriasis, the most interesting is that which occurs on the palms of the hands, and which, being most frequent in those who work with light powders, and other irritating substances, is commonly called bakers', or bricklayers', or washerwomen's itch.

Psoriasis, in all its forms, is difficult of cure. The general condition of the health being corrected by the means that in each case seem appropriate, the remedy which is most frequently successful in cases of long standing is arsenic, in the form of from three to five drops of the Fowler's solution, three times a day, for an adult. Active purging is also often useful, especially in recent cases and in young subjects. Another good remedy is tincture of cantharides, in doses of from three to five drops (for an adult) in water once or more in the day; but the effects of both this and the arsenic require to be carefully watched during their administration, and they must be discontinued as soon as they appear to produce any sickness or heat in the stomach. The arsenic should be taken at meals, if not it is more likely to produce sickness. In addition to these, various other internal means have been recommended, as decoctions of dulcamara, mezereon, and orchis, antimony, sulphur, &c. Indeed, in many cases it is found necessary to try one means after another without any rule, till one is found which produces benefit. External remedies are generally of less value than internal. The most approved are vapour and sulphur baths, and ointments or lotions containing very small quantities of nitrate of mercury, or white precipitate, or creasote, or alkalies. These however can only be employed in the later stages of the disease: in the earlier, the mildest fomentations give relief, and all kinds of irritants must be carefully avoided.

PSYCHE (Ψυχή). Apuleius is the first writer who relates the loves of Cupid (Eros) and Psyche ('Metamorph.', lib. iv., v.). According to his account, Psyche, the daughter of a king, was the most lovely creature that the world ever beheld. People flocked from all parts to see her, and neglected the worship of Venus, who became in consequence jealous of her, and commanded her son to inspire Psyche with love for some mean creature. Cupid, however, instead of obeying the commands of his mother, became enamoured of Psyche, and made her his wife. She was, however, subsequently deserted by him for disobeying his injunction not to seek to behold his face. Inconsolable at her loss, she wandered through the world in search of him, and after enduring many trials and sorrows was at length reunited to him. Jupiter conferred upon her immortality, and her union with Cupid took place with the approbation of Venus and the other deities. A child was soon afterwards born to them, who was called Pleasure.

This tale is now commonly regarded as an allegory, representing the union between the divine love and the human soul. It probably had its origin in the Orphean mysteries. The word Psyche signifies in Greek both "soul" and a "butterfly." We frequently find in ancient works of art Cupid pressing Psyche to his bosom in the form of a butterfly. When Psyche is represented with a human form, the wings of the butterfly are usually placed on her shoulders.

Though Apuleius is the first writer who relates the legend, it is certain that the fable of Eros and Psyche must have been current long before his time, as there are many works of art representing some portion of this subject of a date long anterior to that at which Apuleius lived; though none probably are prior to the Roman period.

PSYCHROMETER (ψυχρος, cold, and μετρον, a measure), a term applied to the wet and dry bulb thermometers used as a HYGROMETER. [HYGROMETRY.]

PTELEIC ACID. An acid of problematical existence said to be produced when mesitic chloral is dissolved in solution of potash.

PTOLEMAIC SYSTEM. A few words of general explanation constitute all that can be given under this head, and we are not now speaking with particular reference to Ptolemy, but of the astronomical part of that system which, founded on early metaphysical and physical doctrines, adopted by Plato and Aristotle, reinforced by mathematical hypotheses drawn from Hipparchus and Ptolemy, received by the Mohammedans and by them imparted to the Christians of the middle ages, was the doctrine universally established in Europe till the 17th century. As a whole it combines the physics of the Aristotelian school, the geometry of Euclid and his successors, the sexagesimal arithmetic of the Greeks, and the astronomy of Hipparchus and Ptolemy, with some slight additions from later names. The geometry remains, the arithmetic has been supplanted by the decimal system of the Hindus; the physics and astronomy stood and fell together; and as under the words Ptolemaic System the astronomy is particularly meant, we only here notice the physical notions so far as they are connected with it.

The early separation of perceptible matter into the four elements of earth, water, air, and fire, with observation of the relative places they appear to assume, led to the formation of an elementary system. Earth (and solids generally) sink in water, while air rises in water, and flame in air. Hence the notion that the mass of the earth is the central body of the universe; above is a region of water, through which rises that portion of earth on which men and animals live. Above this is a region of air, and above this again a region of fire. Nothing is at rest until it arrives at its proper or natural place, and all the motions of a part separated from its whole are rectilinear; fire rises, and bodies fall, in straight lines. Gravity and levity are only the efforts of bodies separated from their natural places to return to them.

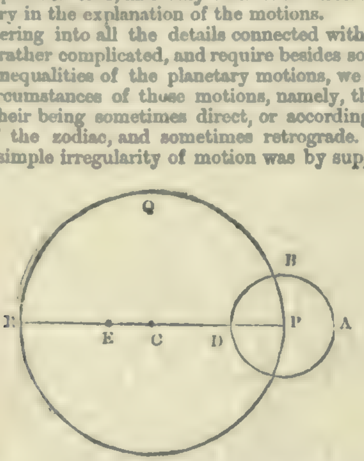
Above the earth and the elementary zones which encompass it, are other successive zones, called heavens. Each heaven contains an immense crystal spherical surface, to which one of the heavenly luminaries is attached, or would be attached, if it moved uniformly in a circle, as it would then do if the crystal sphere were made to revolve uniformly. But the varied motions of the heavenly bodies made it necessary that smaller orbs should be placed with their centres upon the larger ones, as hereafter noticed, and that the planets should move with the smaller ones. It is hardly to be believed (at least so many think) that Ptolemy and the mathematicians received these orbs, in the physical sense, or as anything but hypotheses for representing the actual motions of the planets; it is certain however that the actual solid orbs continued to be received till a late period. Copernicus uses language which has exposed him to some suspicion of receiving them; and even in the final scholium of the Principia Newton thinks it worth while once more to overturn them, as Tycho Brahé had done before him, by showing that if they existed, the comets could not move as they were known to move.

The first heaven is that of the moon; the second that of Mercury; the third that of Venus; the fourth that of the Sun; the fifth that of Mars; the sixth that of Jupiter; the seventh that of Saturn; the eighth that of all the fixed stars. The heavens of Aristotle end here; later theorists add two more, a ninth, to make the precession of the equinoxes, and a tenth, or primum mobile, to make the diurnal revolution. All beyond this is the empyreal heaven.

The office of the *primum mobile* is to revolve from east to west in twenty-four hours, carrying with it (but how, we do not know) the whole of the subordinate heavens, and making all the phenomena of day and night. All the heavenly motions are to be circular and uniform; this doctrine of the Platonic school is the keystone of the whole system. The poles of the primum mobile are those of the equator; but the ninth heaven moves slowly round the poles of the ecliptic, carrying the whole system forward in longitude, so as to give the phenomena arising from the precession of the equinoxes. The heavens of the other heavenly bodies move round with the mean motions of the bodies depending upon them; and this completes the general view of the system.

The details of the heavenly motions were for the mathematicians only, who dropped the orbs, and only took such circles out of them as were necessary in the explanation of the motions.

Without entering into all the details connected with this explanation, which are rather complicated, and require besides some knowledge of the actual inequalities of the planetary motions, we shall take the two leading circumstances of those motions, namely, their not being uniform, and their being sometimes direct, or according to the order of the signs of the zodiac, and sometimes retrograde. One way of explaining the simple irregularity of motion was by supposing the orb of the planet to be a sphere, and revolving uniformly, but not concentric with the earth. Let the earth be at E, and let the circle P Q R revolve uniformly round the centre C, or let the planet P revolve uniformly in that circle. Consequently, the nearer the planet is to E, the faster it will appear to move, and the contrary, that is, a spectator at E will see the planet moving most slowly when at P, from whence the apparent motion will be accelerated until it arrives at R, and retarded while it returns to P on the other side. The circle P Q R is called an eccentric. This hypothesis was a tolerably good representation of the motion of the sun, when E C was taken in a certain specified proportion to the radius C R; and if the sun had been placed at E, it would have made a sufficient representation of the motions of the planets, at least for the earlier periods of observation. But it must be remembered that though an acceleration and retardation would thus be established, it would not be precisely that of the planets, though sufficiently near, as remarked, to represent the results of rough observation.



The mode of obtaining the alternate progressive and retrograde motion is as follows:—Let P be the centre of a circle called an epicycle, and let P revolve uniformly round the earth at C, while the epicycle revolves uniformly round its centre, carrying the planet on its circumference, or while the planet revolves uniformly round the epicycle. Let the epicycle itself move in the direction P Q R, and let the planet on the epicycle move in the same direction, or A B D. If then the times of revolution of the planet in the epicycle be sufficiently great compared with that of the epicycle itself, its retrogradation at D will more than compensate for the progression of the epicycle itself; that is, the planet will appear to a spectator at C to move in a retrograde direction, when it is in the lower part of the epicycle. But in the higher part, at A, both motions conspire to make it appear to move directly. There must consequently be an intermediate point at which the direct motion ceases and the retrograde begins; and near this point the planet will appear stationary.

It is by a complicated use of these methods that Ptolemy succeeds in giving a tolerable account of the angular motions known in his time; but they fail in placing the planet at the right distance from the earth, though they may place it nearly in the right longitude. We imagine that in modern times very few persons have taken the trouble to make themselves acquainted with the details of this system. These may be learnt, with some trouble, from Delambre's account of the Syntaxis ('Hist. Astron. Anc.'), but they are explained with much more clearness in Mr. Narrien's 'Origin and Progress of Astronomy,' London, 1833. Those who would have Ptolemy's own explanation at less expense of time than is necessary to find it in the Syntaxis, should look at his short tract, περὶ ὑποθέσεων τῶν πλανωμένων, which was published with the Sphere of Proclus, by Dr. Bainbridge, in 1620. The physical views may be collected, as well as the mathematical ones, from the 'Philolaus,' the first work of Bouillaud, Amsterdam, 1639. [TROCHOIDAL CURVES.]

PTOSIS is a dropping of the upper eyelid, which the patient cannot by any voluntary exertion raise from before the globe of the eye. In some cases this effect is produced by great inflammatory swelling of the eyelid, with effusion of serum into its tissue; but in those cases to which the name of ptosis is more especially applied, it results from a paralysis of the third pair of nerves [BRAIN, in NAT. HIST. DIV.], or only of that branch of it which supplies the levator palpebræ muscle. [EYE, in NAT. HIST. DIV.] These are in fact cases of local paralysis, and must be treated, without any particular reference to the eye, according to the principles on which paralytic affections in general are managed. [PARALYSIS.]

PTYALIN. An albuminous matter constituting about one-third of the soluble solids of the saliva. It converts starch into dextrin and sugar.

PUBERTY (*Pubertas*), the age at which the period of boyhood or girlhood ends, and that of adolescence begins. [AGE.] The word is derived from *pubes*, which in its primary signification means the down or soft hair that generally begins to grow on young people about that time. Puberty appears at various ages, according to the climate, the circumstances connected with education, and the constitution of the individual. The usual period in this country is from the twelfth to the fourteenth year for females, and from the fourteenth to the sixteenth for males. In the northern parts of the island it is often a year or two later in both sexes. Women in all countries reach the period of puberty one or two years before men; and the inhabitants of warm before those of cold climates. In the hottest regions of Africa, Asia, and America, girls arrive at puberty at ten, or even at nine years of age; in France not till thirteen, fourteen, or fifteen; whilst in Sweden, Russia, and Denmark this period is not attained till from two to three years later.

Occasionally however an extraordinary precocity exhibits itself in the development of both males and females. It is not necessary to dwell at any great length upon instances of exemplification, which may be traced in great numbers in the writings of physiologists who have been curious upon this subject. Those who are desirous of doing so may turn to the 'Journal des Sçavans' for 1688, and the 'Philosophical Transactions' for 1745; and other instances in Dr. Good's 'Practice of Medicine.'

The period which commences with puberty is, both as regards the mind and the body, one of the most important epochs of human existence; for, says Dr. Copland ('Dictionary of Practical Medicine'), during it the natural development of the sexual organs imparts a health and tonic excitement throughout the economy, bringing to their state of full perfection all the organs of the body, and all the manifestations of mind, excepting those that are derived from experience. It is chiefly during this period of life that the mind becomes stored with ideas, derived both from the learning of the ancients, the science of the moderns, and the arts and accomplishments of highly civilised life; and is more particularly and more ardently engaged in decomposing the information thus acquired, and recombining it in new and useful attractive forms.

PUBLIC HEALTH. [SANITARY LEGISLATION.]

PUBLIC LIBRARIES. [LIBRARIES.]

PUBLIC POLICY. This expression sometimes occurs in the reports of law cases, and sometimes the expression "policy of the law" occurs; neither of these expressions has a sufficiently definite meaning. An example will best explain how they are applied. One man may agree with another for a certain valuable consideration to give up to him some trade, art, or business, and agree that he will not carry on the same within the realm, with the object of securing to the purchaser all the benefit which can be derived from his bargain. If he who has received the money happens to break his contract by commencing the same trade, art, or business in a distant part of the realm, as at the Land's End or Newcastle-on-Tyne (the original place of business being London), and an action be brought on the contract, it could not be maintained, because the contract itself was *against public policy*, which would be explained to mean that the public ought not to be deprived of a man's services by such an unreasonable contract. Yet if the contract were that the trade or business should not be exercised within a certain limited distance of London, the contract would be valid.

PUBLICA'NI. The publicani were a body of persons in the Roman state who farmed the public revenues (*vectigalia*), from which circumstance apparently their name is derived. ("Publicani autem dicuntur qui publica vectigalia habent conducta," 'Dig.,' 39, tit. 4, s. 12.) They were numerous as early as the 6th century of the republic, and they continued to exist under the emperors. The publicani formed various societies or partnerships, which had a corporate character. Each societas had a magister, or chief manager, at Rome, and a deputy magister (*promagistro*), with numerous associates and assistants, in the provinces. [PROVINCIA.] The revenues, which were chiefly leased to the publicani, were tolls, harbour duties, and the scriptura, or the tax that was paid for the use of the public pasture-lands. The publicani had their under-lessees (*portitores*, τελῶναι, Luke v. 27, 29) and collectors. Numerous slaves were also employed by them in collecting the taxes; and this body of men was comprehended under the term of a *familia publicanorum*. In our translation of the New Testament these inferior officers are called "publicans," and are mentioned together with "sinners," a distinction to which they might be partly entitled for their occasional oppressive conduct, and partly to the general dislike of all the world to tax-collectors. It appears that Matthew, who was a Jew, was a publican (Matt. ix. 9), the only civil employment held by a Jew under the Romans.

The publicani undertook to pay fixed sums for the taxes of a particular district or place. The contract was often made by a single person on behalf of himself and others. It was the business of the censors to let the taxes. The publicani gave security to the state for the due performance of their contract; and their property, as well as that of their sureties, was liable to the amount of their obligations.

Among the remedies which the publicani had against those who were bound to pay vectigal, was the *pignoris captio*, which seems to have been a kind of distress (Gaius, iv. 28); but after the old forms of action were changed, it was not usual actually to seize the property, but a fiction was introduced into the formula, by virtue of which the person who owed the vectigal might be condemned in a sum of money equal in amount to what he must have paid in order to redeem his property if it had been seized.

PUERPERAL DISEASES. Under this term are included all those diseases which arise out of the state of pregnancy: they are not, however, as the name would seem to imply, peculiar to this condition, but incidental only; and they are so far modified by it as to require some allusion to their character and mode of treatment. Among the most alarming of these diseases, and the earliest to make their appearance, are puerperal convulsions; they consist of epileptic seizures, and their character differs in no respect from the ordinary epileptic fits already described in the article EPILEPSY: we therefore shall merely observe in the present place, that convulsions are liable to occur at any time after the sixth month of utero-gestation; but for the reasons about to be stated, the majority of cases are met with during labour. When they occur after delivery, they are generally connected with a loaded state of the large intestine, or with a state of exhaustion from hæmorrhage. The cause of these attacks must be looked for in the state of the viscera and large blood-vessels at this period: during gestation, these parts are subjected to a constant and increasing degree of pressure from the gravid uterus, the natural tendency of which is to produce local congestion of the circulating fluid, and an undue accumulation of the excretions within the intestines. At the time of parturition this pressure is materially augmented by the contractile efforts which are made to expel the infant; and the mechanical obstacle thus offered to the flow of blood through the abdominal aorta, determines it in unnatural quantity to the brain. Hence this state of things, if not remedied, may not only produce the disease we have just been considering, but may even give rise to apoplexy. The treatment is obvious, and consists in relieving the vascular system by general and topical bleeding, and unloading the intestines by brisk cathartics.

A recent writer attributes puerperal convulsions to the presence of urea in the blood.

But by far the most important and the most dangerous of puerperal diseases is puerperal peritonitis [PERITONITIS], called also puerperal inflammation, puerperal fever. It usually attacks women a few days after delivery, and seems to have no connection with the duration or the severity of labour. This fatal disease varies so much in the type of the inflammation as to be scarcely recognised as the same affection in different individuals and at different periods, the accompanying fever being sometimes strictly inflammatory, and at other times typhoid. In its most dangerous form it is characterised by a remarkable prostration of the vital powers, and by a countenance expressive of extreme anxiety and distress. The pulse is frequent and feeble; the abdomen tympanitic, and unable to bear the slightest pressure; the bowels are constipated, and vomiting is not an unfrequent attendant. As the disease proceeds, the lochial discharge and the secretion of milk are suppressed; and towards its termination, a total cessation of pain sometimes occurs, and the patient dies, often in full possession of her consciousness to the last. This severe form of puerperal fever is most frequently epidemic, and many believe it to be highly contagious. The lesions met with in this disease are chiefly manifest in the peritoneum; but in the worst cases, the substance of the uterus itself, and the large veins in its vicinity, present evidences of inflammation. The treatment of puerperal fever is peculiarly difficult; "every case," observes one of our most celebrated accoucheurs, "must be isolated and studied alone, and looked at by itself, and its management must depend upon its type and its stage." Bleeding, general and topical; counter-irritation, by means of blisters or spirits of turpentine, applied to the abdomen; purging, by the exhibition of the last-named medicine, or by large doses of calomel; and the latter, given to excite ptyalism, have been the principal remedies used for combating this formidable malady. But the prostration of the vital powers is in some cases so extreme as to afford us little chance of putting into requisition the only means which we possess of combating the inflammatory symptoms.

A form of disease sometimes occurs after delivery which, from its resemblance in some particulars to the one we have just alluded to, requires notice. It is due to stomachal and intestinal irritation; and is ushered in by rigors, followed by great heat of skin, a full and frequent pulse, and loaded tongue. The abdomen may be tumid and painful on pressure, and the head may be affected by symptoms of phrenitis, as intolerance of light, noise, wakefulness, and delirium. The affection of the head and that of the abdomen frequently co-exist or alternate in the same case; and this conjunction of the two affections serves to assist in the diagnosis between peritonitis and the present complaint. As it is of the greatest importance in a therapeutic point of view to distinguish puerperal inflammation from intestinal irritation, much may be learnt by the exhibition of large injections of warm water, an examination of the evacuations, and an observation of the effects thus produced upon the disease. In intestinal disorders, the fæces will be found to be scybalous, or at least offensive and dark-coloured, and in large quantities; and the relief obtained will be found to depend upon the proper evacuation of the bowels. Another characteristic of intestinal irritation is the susceptibility to fainting upon blood-letting. The treatment of this disorder may be summed up in the words of Dr. Marshall Hall. "In peritonitis," he observes, "the freest blood-letting must be aided by purgative medicines; whilst in intestinal irritation, the freest and fullest evacuation of the intestines must be aided by blood-letting; for although both blood-letting and purging are to be used in every case, yet the former is the remedy in inflammation, and the latter in intestinal irritation." In describing the last-mentioned disease, we have alluded to the combination of cerebral symptoms, which so frequently are present. This disturbance of the intellectual functions is sometimes so great and so continued, as to lead to the supposition that the brain is the seat of some active inflammatory disease; and were we, acting upon this supposition, to have recourse to antiphlogistic remedies only, we should probably lose our patient. This alarming disorder has been termed puerperal insanity, or puerperal mania. It comes on rather insidiously: there is a little excitement during the day and sleeplessness at night; then delirium, and then actual mania; the pulse is somewhat accelerated, the tongue furred, the skin hot, the bowels costive, and the secretion of milk diminished. It seems to arise from a combination of causes acting upon an originally irritable temperament, but rendered still more so by intestinal disorder and hæmorrhage, or by the debility consequent upon suckling. Blood-letting in these cases is generally fatal; the treatment consists in regulating the bowels and preserving extreme quiet of mind and body, with a nutritious but not stimulating diet.

When speaking of puerperal fever, it was observed that the large veins in the vicinity of the uterus frequently presented traces of inflammation. Uterine and crural phlebitis, however, occurs as a distinct disease, and has been described under the terms of phlegmasia dolens, œdema puerperarum, the white swelling of lying-in women, &c.; but it is only within a few years that the true nature of this disease has been fully understood, having been first pointed out to the profession by Dr. Robert Lee. It may appear as early as the fourth day after delivery; but, in the majority of cases, it is not till the second or third week that it makes its appearance; and, in many instances, attacks women who are recovering from puerperal fever. It is ushered in with rigors, and these are succeeded by heat, thirst, and other symptoms of pyrexia. There is a sense of pain, first experienced in the uterine region, and gradually descending in the course of the iliac and crural veins down one leg, accompanied by swelling, and great tenderness upon pressure along the course of the vessels, which are hard as a cord, and roll under the fingers. In some cases an erythematous redness of the integuments of the limb is met with; but in the majority they are smooth, shining, tense, and colourless. The power of moving the limb is completely lost, and it is greatly and uniformly swollen throughout its whole extent. Sometimes, after the inflammation has subsided in one limb, the other is attacked in a similar way. The pain and febrile symptoms usually diminish within a few days after the occurrence of the swelling; but sometimes the pain is excruciating throughout the whole period of the acute stage of the disease. The duration of the acute stage is various in different individuals; in the greater number of cases it terminates in two or three weeks; but the limb still remains powerless and œdematous. In some women the limb does not return to its natural state for many months, or years, or even during life. The appearances on dissection which are met with in this disease are similar to those which characterise inflammation of the veins generally. The causes of this affection are supposed to be owing to the orifices of the veins in the lining membrane of the uterus being left open after the separation of the placenta, by which a direct communication is established between the cavities of these veins and the atmospheric air. The treatment of phlegmasia dolens consists in the local abstraction of blood by leeches applied to the groin, and in the course of the large venous trunks of the limb; hot fomentations to the part, and the administration of diaphoretics and saline purgatives. After the inflammatory symptoms have subsided, the limb may be supported by a bandage, and slight frictions made use of.

There is a disorder occasionally met with in the puerperal state, which, from not being mentioned in the article HÆMORRHAGE, must be alluded to in this place. The symptoms about to be detailed are owing to loss of blood, uterine hæmorrhage during and shortly after parturition being not an unfrequent occurrence. The more immediate effects of hæmorrhage are fainting; and where the loss of blood has been great, this symptom is sometimes so prolonged as to be not only dangerous, but fatal. It is the more remote consequences of loss of blood that we are to speak of in this place: we have seen already how a combination of this with intestinal disorder and other irritating causes gives rise to puerperal mania; we shall now view the effects of hæmorrhage as they are met with uncombined with the conditions previously alluded to. This condition of system has been called by the French pathologists a state of anæma, and is characterised by a pallid condition of the skin; great nervous excitability; a throbbing of the temples; vertigo; tinnitus aurium; a frequent, jerking, compressible pulse; a great tendency to faint on the slightest exertion, or in the upright position; palpitation of the heart; halitant respiration; and, generally, great thirst. The treatment to be adopted in anæmia from loss of blood, consists in maintaining a perfect quiet of mind and body, in a free exposure of the patient to fresh air, a mild but nutritive diet, and a regular but not an over-active state of the bowels. The symptoms we have just enumerated as arising from loss of blood are sometimes met with, in a mitigated form, at a much later period of the puerperal state, and arise from the drain occasioned by superlactation. The treatment of these cases is more simple, and consists generally in the weaning of the child, the adoption of a more nutritive diet, and change of air. With respect to what are called milk-abscesses, they arise from the inflammation consequent on over-distention of the lactiferous tubes, and require the same mode of treatment as is adopted in abscess when it occurs in other parts than the breast. [ABSCESS.] They are best prevented by permitting the infant to suck within a few hours after delivery, and by repeating this act frequently. When the secretion of milk is excessive, the bowels should be kept freely open by saline purgatives.

PULLEY. A machine used in the arts for the purpose of transmitting power, which consists of a case with one or more openings, in which a similar number of sheaves revolve upon an axle; the case or block is surrounded in the direction of its length by a band ending in a hook able to be fixed to any point of support. The cord or chain working upon the sheaf, or sheaves, either increases the power exercised, whilst it decreases the velocity of movement, according to the principles of mechanics; or it simply changes the direction of the movement transmitted. Pulleys are either made of wood, or of metal: the former being almost exclusively used for ship-building. In the wooden pulleys the blocks are usually made of elm, the sheaves of lignum vitæ, and the axles of either wood, or of iron; in metal pulleys the blocks are made of iron, the sheaves of brass, the axles of iron or of steel, and the bushes of brass. The proportions of the various parts of a pulley are regulated by the width of the sheaf, and this module itself must be chosen so that the cord or chain shall ride easily on its gorge, without working against the sides; the proportion of the diameter of the axle to that of the pulley must be made as small as is consistent with the strength of the machine, and the sheaves must be so truly bored as to allow of their revolution without any friction against the sides of the blocks.

The term pulley is likewise applied to some of the narrow band wheels used for the purpose of driving machinery gearing, especially when they are of the description technically known under the name of fast and loose pulleys, or those in which one of the assemblage of wheels is made to revolve freely upon the shaft, without being able to communicate any motion to the latter. In these cases the velocity of the axle driven by the intervention of the pulley will be regulated by the proportions between the diameters of the pulleys. [MACHINE.]

PULMONIC ACID. Synonymous with PNEUMIC ACID.

PULPIT. This term affords a striking instance of the great change of meaning and application which words frequently undergo, for, exclusively of the Latin termination, it is identical with *Pulpitum*, which signified that part of the Roman stage (distinguished from the orchestra) on which the actors recited and performed their parts. The French *pupitre* and the English *pulpit* both come from the same source, but are dissimilar in signification; the former meaning merely a reading-desk, and *chaire* (*cathedra*) being the term that corresponds with our English pulpit. The *ambo* of the early Christians appears to have been different both in form and purpose from pulpits afterwards used for preaching, it being rather a low platform on which parts of the service were sung or recited. The most ancient pulpits now existing are supposed to be those in S. Lorenzo fuor delle Mura and S. Clemente at Rome; and these and other early pulpits of the same kind are of marble, with inlaid or mosaic compartments. In the church of S. Lorenzo at Florence, and several other modern basilicas, there are two pulpits, one on each side of the nave. Great cost both of material and workmanship was frequently bestowed on pulpits; and some of them rank among the most celebrated monuments of art of their period. The pulpit in the baptistery of Pisa, by Niccola, is hexagonal, and supported on seven columns, one at each angle and a central one. Giovanni Pisano executed that in the nave of the Duomo at Pisa, besides which there are two others in the same church, on the opposite sides of the choir. The *Pergamo* of Santa Croce at Florence, by B. da Majano, is greatly extolled by Vasari for the beauty of its reliefs and sculptures. The two *pergami* in S. Lorenzo at Florence, are the work of Donatello; and of the mastery of composition displayed in their reliefs some idea may be formed from the specimen given of them in Cicognara's 'Storia della Scultura.' Notwithstanding the richness of such pulpits, and their elaborate execution, their general forms are not always the most pleasing or appropriate.]

For a long time the pulpit appears to have been treated as an architectural feature, being constructed, if not of marble, of the same material as the rest of the interior. Among numerous other examples of Gothic stone-pulpits may be mentioned one that has been much admired, though it is very impure in style, in the nave of Strasburg cathedral. One of the most celebrated as a performance of art is the magnificent oak pulpit in the nave of St. Gudule, at Brussels; the whole is elaborately carved, and the pulpit itself is supported by figures representing Adam and Eve expelled from Paradise.

Of stone-pulpits we have only a few remaining in this country; but there is one in Bristol cathedral dated 1624, another in Worcester, drawings and details of which latter are given in Pugin's 'Gothic Specimens;' and others in Huish-Episcopi, Somersetshire; Coombe, Oxfordshire, &c.; but old carved wooden pulpits are much more common. The Worcester pulpit, and a stone pulpit in the outer court of Magdalene College, Oxford, are instances of what may be termed *oriel pulpits*, being made to project after the fashion of an oriel, from a pier or wall, and similarly corbelled below, instead of being supported from the ground. Another, still more ancient and curious—and we may add, more beautiful—is that at Beaulieu, Hants, which projects from an elegant open Gothic arch, and is supported, not on a corbelled and moulded oriel-stool, but on a short reversed spire, whose angles are decorated with small pillar-shafts, and the sides between them with foliage. Besides pulpits of this kind in the courts and cloisters of religious houses, there were others called *preaching-crosses*, from which sermons were delivered in the open air: Paul's Cross is a celebrated and well-known instance.

PUMP. A machine used in the arts, and in the ordinary business of life, for the purpose of raising water from a lower to a higher level; or for the purpose of forcing it through pipes to be distributed as may be required. Pumps are occasionally used in similar manner, in dealing with other aqueous fluids, with trifling modifications in their details, according to the nature of the fluids; and a peculiar class of pump is employed for the purpose of either removing, or of distributing air or other gaseous fluids. The general principles of the pumps applicable to the respective kinds of fluids, are however so closely allied, that it may suffice here to notice only the more common descriptions of *water* and of *air-pumps*, referring occasionally to some of the most important modifications to which they are subjected in order to adapt them to particular circumstances.

Water pumps are divided into two general classes, called 1st, *suction pumps*, or 2nd, *forcing pumps*, according to their mode of action. The suction pumps are those in which the atmospheric pressure is made use of to force a column of water to rise in a tube, from which the air has been withdrawn in such a manner as to leave a vacuum in its interior. The forcing pumps are those in which a mechanical effort is applied to the water to raise it to the required level. Evidently the power of the suction pump is limited in this respect; namely, that the column of water cannot rise beyond the level at which the weight of the column of water balances the weight of the atmosphere; whereas the power of the forcing pump is only limited by the dynamical effort employed, and by the strength of the machinery itself. Suction pumps are therefore only used in simple cases, and where the water has not to be raised to any great height; at times, combined suction and forcing pumps are used, but wherever large volumes of water have to be moved, forcing pumps are the only ones which are habitually employed. The common lifting pumps are, it may be added, simply those modifications of the forcing pumps, which are used in cases where the quantity of water to be raised is not very great, or where the height above the limit of action of the suction pump is not very considerable.

The component parts of all kinds of pumps are, 1°, the cylinder in which works, 2°, the piston; 3°, the suction, or feed-pipe; 4°, the various clacks or valves; and 5°, the delivery pipe. In the large pumping works for town supplies, there are placed upon the delivery pipes either some air vessels, or some stand pipes or water towers, for the purpose of equalising the pressure on the distributing pipes, and of obviating the hydraulic jar produced by the alternate motion of the piston in its up and down strokes. The motive power used in working the pumps, and the various details of the pipes, pistons, piston-rods, valves, &c., are so numerous that it will only be possible here to describe some of the most important modifications of them.

The cylinder is usually circular in its transverse section, although in some cases it is made quadrangular, or even polygonal. For small lifts it may be made either of wood or of metal; but the former material wears away too rapidly for works destined to be used for any length of time. The use of wooden pumps is, therefore, almost exclusively confined to agricultural purposes, or to ships, principally on account of their economy in the first instance; whilst cast-iron or brass, is almost exclusively used for the cylinders of pumps employed in industrial operations. Of whatever material the cylinder may be made, it is, however, essential that it should be perfectly straight and true in its bore; even when the piston does not work in close contact with it. The power of a pump, of whatsoever description it may be, depends upon the inner diameter of the cylinder. It is considered to be small, when the diameter is less than from 5 to 6 inches; it is considered to be large when it exceeds 1 foot in diameter; and it is only in the great mining operations, or in municipal water supplies that the diameter of pump cylinders exceeds 2 feet. The length of the cylinder only exceeds that of the stroke of the piston by a small quantity.

The piston is the most important part of the machinery of a pump; it is the part which requires the greatest skill in its manufacture, and upon whose correct action the success of the whole machine depends; under these circumstances, as might have been expected, it has been modified in the greatest possible variety of manners. If the piston raise the water during its ascent, or its descent only, its action is said to be *single;* if on the contrary, it should raise the water by both those motions, the action is said to be *double.* The ordinary suction pumps have wooden pistons, working hermetically against the sides of the cylinder, but bearing a clack in the centre, through which the water rises on the down stroke, to be lifted on the up stroke to the point of discharge. A more complicated description of piston for the purpose of raising the water on the up stroke is used in the lifting pumps, and they have to support the weight of the column of water above them. In the ordinary forcing pump, however, the piston only forces the water forward on the down stroke; but in the double action forcing pumps, the water is raised by both the up and the down strokes, by a peculiar arrangement of the clacks and delivery pipes, to be noticed hereafter.

The pistons of common pumps are made ordinarily of a piece of hornbeam, to which the rod is attached by a kind of stirrup-handle, and which is pierced by a circular opening, *a* (*fig.* 1), whose diameter is equal to about half that of the piston. In the simpler forms of the suction and forcing pumps, the piston is made solid, and the water raised into the barrel or cylinder by the up stroke of the piston is forced on the down stroke to pass through a foot-valve placed upon the rising pipe fixed by the side of the cylinder, *b* (*fig.* 1); there is a valve also placed at the top of the arrival pipe, and both these valves are made so as only to open upwards. Under whatsoever circumstances the pistons may work, they are made to fit closely against the sides of the cylinder, by means of a species of packing, in order to cut off any connection between the air above and below them; but of course, whilst thus excluding the passage of air, they must not give rise to such an amount of friction as to cause any serious waste of labour in pumping. The packing may consist either of leather, spun-yarn, or of some anti-friction metal, acted upon by an internal spring.

Fig. 1.

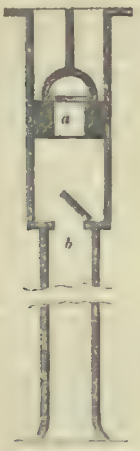


Fig. 2.

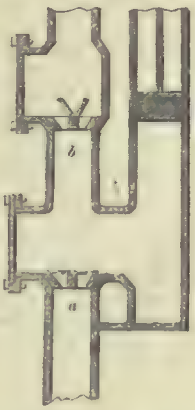

The valves of pumps are known under the names of clack-valves, or of spindle-valves. The former are in fact flat plates of wood, metal, or leather, working on a hinge in only one direction, *a* and *b* (*figs.* 2 and 3), fitting closely upon the seating or face of the valve, and sufficiently stiff to resist deformation by the weight above them. The latter are either portions of cones, or small globes kept in their positions by means of spindles traversing their axes; upon the spindle a stop is placed to regulate the dimensions of the passage way. There are, however, some modifications of the spindle-valves, in which lateral guides are substituted for the central spindle, so that perhaps the term *seat*-valves would be more generally applicable to the class; and in the pumping-engines on the Cornish system a very complicated system of machinery is introduced, under the name of the equilibrium-valves, to regulate the admission of steam to the cylinders. The consideration of these steam valves hardly comes under this portion of our subject, but it has been thought necessary to allude to them in passing, as being connected with pumping machinery. When very foul water has to be pumped, or when a very heavy column of water has to be raised, there are also introduced some special forms of valves, such as the ball-and-socket valves, &c., *a* (*fig.* 4), which it would be impossible to describe in detail. It may suffice here simply to add that, inasmuch as the valves are precisely the portions of a pump which are the most likely to get out of repair, it is essential that means should be provided for obtaining easy access to them. This is usually effected by swelling out the pipes immediately above them, and by placing a moveable cover over the increased space thus enclosed.

Fig. 3.

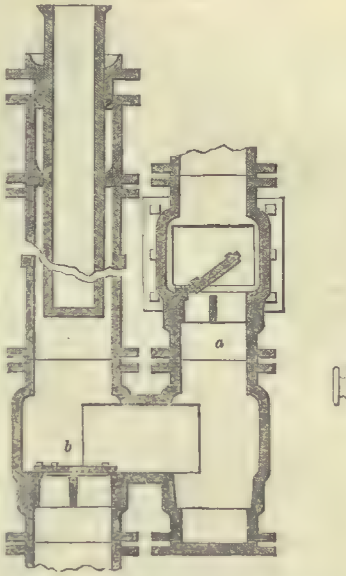

Fig. 4.

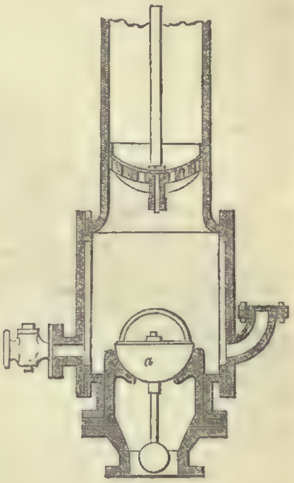

The suction and rising mains do not require any special description; for all that is required in the former, in addition to the ordinary conditions of pipes, is, that they should have some provision made at their lower end for keeping out large extraneous substances, and that the valve-seats and chambers of the upper end should be provided for. In the rising mains, the junction pieces, the valve-seats, and the delivery cisterns, are the only portions which require special castings. The suction pipes can rarely be made of more than 26 feet in length, and their diameter should not exceed more than $\frac{2}{3}$ or $\frac{1}{2}$ of that of the cylinder, without however falling below the latter dimension. The diameter of the ascending main should bear about the same proportions; its length need only be regulated by the power able to be applied to it; in some mines, ascending pipes of 750 feet in length are used.

In D'Aubuisson's admirable treatise, 'De l'Hydraulique,' the reader will find (at page 511, edition of Paris, 1840), the various conditions of the respective kinds of pumping machinery discussed in the most elaborate and philosophical manner. In this cursory notice it may suffice to state that D'Aubuisson shows that an ordinary suction pump cannot work efficiently at a greater distance, measuring from the underside of the piston to the surface of the water at the lower level, than 12 *b*, in which expression *b* will equal the height of the barometer at the place observed. This distance will vary between 30 feet and 26 feet 8 inches, according to the elevation; but the effective height will be further diminished by the interval between the bottom of the stroke and the foot valve; the interval in question should be made as little as possible, and should not exceed one-tenth of the diameter of the cylinder.

There is in all descriptions of pumps a certain amount of power required to be exerted, in addition to that which is necessary to raise the quantity of water to be delivered. In an ordinary suction pump this additional power is, on the ascending stroke, composed of the weight of the water above the piston, of the weight of the piston itself, and of the friction of the various parts. D'Aubuisson calculates that, in well-made pumps, the sum of these elements is equal to about $\frac{1}{11}$ h more than the real statical weight resting on the piston. On the descending stroke the piston meets with a resistance arising from the contraction of the fluid vein, when the water passes through the clacks, and from the friction of the packing against the sides of the cylinders; as this resistance is, however, considerably less than that which is overcome on the ascending stroke, little attention is paid to it. In cases where large quantities of water have to be raised by pumps of this description, it is customary to couple them, in order to equalise the power exercised during the upward and downward strokes, by making the motions of the respective pistons reciprocally alternating. The two pumps pour their water into the same head, which thus gives nearly a constant discharge.

The resistances involving loss of power are much more numerous and more complicated in the case of force pumps, for in them not only is the whole column of water to be set in motion, but there is a loss of useful effect: 1st, in consequence of the contraction of the fluid vein at the foot valves; 2nd, in consequence of the bends, or changes of direction in the line of flow; 3rd, in the weight and friction of the valves; 4th, in the friction of the pumping machinery; and 5th, in the friction of the ascending column of water against the sides of the pipes, and in the inertia of the water itself. D'Aubuisson gives the formulæ usually adopted to calculate the value of these resistances (pp. 519 to 525); but he prefaces them by saying, that it is impossible to determine them rigorously. It may then suffice to say, that in some mining-pumps, where the lift is very great, the sum of these resistances is such as to reduce the useful effect of the pumping machinery to about one-half of the power exercised. In large force pumps the pistons are usually made of the description known technically by the name of *plungers;* that is to say, they are formed of hollow metal cylinders working in a stuffing-box, but with a small annular space between their sides, and those of the cylinders. Theoretically, the quantity of water raised by each stroke of the plunger would be equal to its sectional area multiplied by the length of the stroke, but in practice there is found to be a considerable loss of effect; and in cases where plunger pumps are used in conjunction with lifting pumps (as in deep mines), it is customary to make the former of $\frac{1}{15}$th larger diameter than the latter. In the force-pumps of very deep mines it is necessary to counterbalance the weight of the piston rods, and to take great precautions to prevent their becoming bent under the jars they are exposed to by their own vibration.

The action even of connected pumps being of necessity of an intermittent character, there is introduced near the point of delivery a large vessel, called the *air vessel*, into which the water is forced in greater quantities than can be discharged by the outlet valve, during the period of inlet. The water then accumulates in the air vessel, and compresses the air contained in it, sometimes even to the extent of producing a pressure equal to three atmospheres. Of course when the water ceases to enter through the valve connected with the piston, the reaction of the compressed air maintains the discharge through the foot valve, and thus the discharge is rendered almost continuous. The air-vessels also diminish in a notable manner the hydraulic jar on the rising main, produced by the intermittent action of the pumping machinery.

In addition to the suction and forcing pumps, there are several descriptions of machines used for raising water, such as the chain pumps, norias, Archimedian screws, scoops, bucket wheels, Persian wheels, flash wheels, rotary pumps, &c.; and perhaps it would be preferable at once to notice them, even though in some cases the machinery can hardly be considered to come under the strict definition of the word "pump." Thus, the chain pump consists of a series of flat boards which are attached to an endless chain, and the latter works upon fixed wheels at the top and bottom of the course; the flat boards in ascending pass through a cylinder, and lift in it a column of water. The Noria is a machine much used in the East for irrigation purposes, and consists of a series of earthen pots ranged upon a rope, working also on fixed wheels; so that the pots dip into, and raise the water from the bottom of the well, to discharge it whan they pass over the top wheel. The Archimedian screws, as their name implies, consist of a series of threads, or worms, fixed upon an axis of rotation bearing on a fixed pivot at the lower end, and having a winch handle at the top. There are usually three threads working in a species of close fitting race, or channel, open at the top; the diameter of the thread is usually made from 13 to 26 inches, but occasionally it has been made as much as 6 feet; the angle made by the thread with the axis of the central shaft (which, it may be added, is usually equal in diameter to $\frac{1}{3}$rd of that of the thread) varies between 45° and 78°; but in practice an angle of 60° is found to be the most advantageous. The axis of the central shaft is usually placed so as to form an angle of from 30° to 45° with the horizontal line. These Archimedian screws are much used in Holland for drainage works; they are driven by wind-mills, and raise the water very economically, provided the lift be not more than 15 feet. On the Sambre and Meuse canal a screw of 5 feet 4 inches diameter, and 21 feet 6 inches lift, worked by a steam engine, has given very satisfactory results.

The scoops are, in fact, large troughs fixed at one end on an axis, and connected at the other to a balance beam, to which an alternate motion is communicated from some extraneous motive power; so that the scoop is made to dip into the water when the beam is at its lowest point, and to discharge the water over the line of its own fixed axis when the beam rises. These engines are applicable to lifts of from 12 to 15 feet, and they certainly work with very economical results. The bucket wheels are, in principle, very similar to the norias, and are used in Switzerland, and in some parts of Germany, for irrigation purposes; they consist of a number of small buckets, arranged on the periphery of a wheel made to revolve in water, so that the buckets become filled at the bottom of the revolution, and discharge their contents at the top of the same. The dynamical results of these wheels is not very satisfactory, but they do not require frequent repairs, nor do they require attendance; conditions which make them desirable for the class of work they are usually applied to. Persian wheels have been occasionally used for raising water from the interiors of coffer-dams, but are now almost entirely abandoned; they consist of a series of helicoidal channels formed in large wheels, which are made to dip in the water, and as the wheel revolves the water finds its way to the centre of the wheel, where an outlet is provided for it. It is very rarely that the lift of these wheels exceeds 12 feet. The dash wheels are, however, the machines of this description of the most common use, and in the polders of Holland they may be seen in almost every direction in connection with windmills, whilst in our own fens they are as frequently employed with steam as a motive power. They consist of a series of floats fixed on the periphery of a wheel made to revolve in the water with great velocity, and the tangential force thus applied to the water itself is sufficient to raise it to a height of nearly 20 feet. There is a very efficient wheel of this description at work in the Deeping Fen, near Spalding, set in motion by a steam engine of 80-horse power; the wheel is 28 feet in diameter, with floats measuring 5½ feet by 5 feet moving with a velocity of 6 feet per second on the average; the quantity of water discharged is 165 cubic feet per second, raised 5 feet. At Ten-mile bank, near Littleport, in the Isle of Ely, there is a wheel of 40 feet in diameter also moved by steam.

The Rotary, or Centrifugal, pumps are those in which a rectilineal vertical motion is communicated to the water to be raised, by means of a wheel, bearing a series of fixed arms rotating at a high velocity in a close drum, and receiving its supply through the apertures in the side of the drum close to the axis. The shape of the arms has a very material influence upon the useful effects of these pumps; and, after many experiments, it has been found that the most advantageous form to be given to them is to curve them backwards to the direction of the movement, so as to form a tangent to the circumference of the wheel at the points where they intersect it. Amongst the most valuable forms of these centrifugal pumps for drainage purposes, those manufactured by Mr. Appold, or by Messrs. Gwynne and Co., are those most generally known; and perhaps it may be desirable to add that the latter work with the smallest loss of power compared to the useful effect with small lifts: Appold's pumps, however, present more satisfactory results when higher lifts are required. All these engines are inferior to the best forms of force-pumps when large volumes of water have to be raised to great heights; and their use would appear, in their present forms at least, to be most advantageously limited to lifts of about 30 or 40 feet vertical as a maximum.

The discussion of the motive powers to be applied for the raising of water by pumps, or other machines, will be more conveniently reserved to WATER SUPPLY.

In Air-Pumps the objects to be obtained are twofold:—1st, to exhaust the air under a receiver, for the sake of obtaining a vacuum; and 2nd, to condense the air so as to produce an increased pressure upon the enclosed surface. The former object is sought to be obtained in philosophical experiments, or in chemical or physical investigations; the condensation of air has lately been applied to many important operations in the arts of construction. The exhaustion of the air is effected by means of one or more pistons working through air-tight cylinders, and provided with a series of valves which allow the air to pass from the receiver to the exterior, but without admitting any return; so that the air of the interior becomes more and more rarified in proportion to the effort employed, and the perfection of the machinery. No instrument of this description has yet secured a perfect vacuum, though from what has been said in the article AIR-PUMP, some remarkable results seem to have been attained, approximating very closely to that condition. As the mechanism of air-pumps for exhaustion has been described in the article thus referred to, it will suffice here to state that in machinery they are principally used for the purpose of overcoming the resistances opposed by the steam left in the cylinders of steam engines, and for removing the contaminated air in mines, or in diving-bells. The condensing air-pumps, in their turn, are made with valves opening inwards only, so as to allow air to be forced into the receivers without being able to return. They are employed for the purpose of forcing air into diving bells, into blowing machinery of mines, and latterly into the cylinders used for making the foundations of bridges upon running sands. In the latter case the compression of the air reaches to the extent of an effort equal to at least three atmospheres, and the workmen are obliged to carry on their operations in a medium of that density. A description of the machinery of this description used in the Rochester bridge, was given some years since by Mr. Hughes, who executed the works of that remarkable monument, and the system has since been applied with success in the cases of the bridges of Kiel over the Rhine, and of the railway bridge over the Theiss in Hungary. Coulomb appears to have been the first person to introduce this system in a *mémoire* addressed to the Academie des Sciences in 1778; and the French engineers have since that period frequently employed it in hydraulic, or in mining operations, when the pressure to be overcome has not exceeded the above quoted limit of three atmospheres.

Ships' Pumps. For a number of years the chain-pump, consisting of a series of metallic discs, regularly arranged upon a bar chain, each disc acting as a piston, was the only one in use on board large ships, and it may still be seen in several of our sea-going old line-of-battle ships, although new chain-pumps are no longer fitted in her Majesty's service.

Pumps of various descriptions are in use both in the navy and merchant service—each form having its qualifications. That much is required from them may be gathered from the fact that a steamer of moderate size requires a ton and a quarter of condensing water per hour for each horse power; and therefore in case of serious leak it is of vital importance to obtain this quantity for injection into the boilers from the hold of the ship by means of the engine itself. Her Majesty's ship Phœnix not long since was saved from foundering in the Bay of Biscay, by thus injecting from the bilge; but had the injection pipe been unprotected from chips, &c., the ship's pump alone could not have saved her.

The following may be considered to be the necessary qualifications of a ship's pump, namely, it should be 1, easy to work; 2, give a continuous stream of water of the greatest possible quantity; 3, be not easy to choke; 4, be so simple in construction as to be easily taken to pieces, and repaired at sea; 5, the valves should be of durable material; 6, so constructed as in case of choking to admit of the ready removal of the bottom box without withdrawing the piston or pistons.

Among the best pumps in use at sea, may be mentioned Massey's double action; Dowton's many-pistoned; Robertson's double action twin pump; Redpath's pump; Suffield's india rubber valved pump, &c. From among these, on account of its very peculiar construction, and from its having been recently tried successfully against several other forms of pumps on board her Majesty's ship Fisgard, we give below an illustration of Redpath's, of Limehouse.

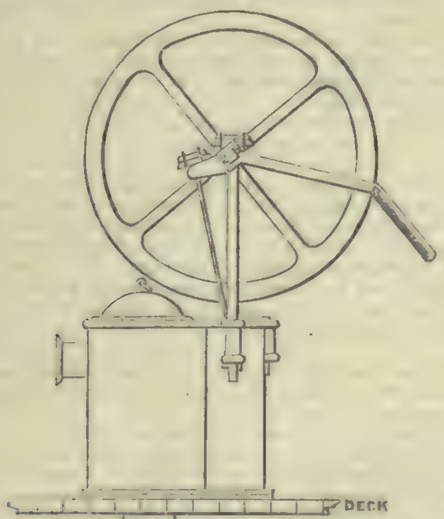

Fig. 5.—Redpath's Patent Pump.

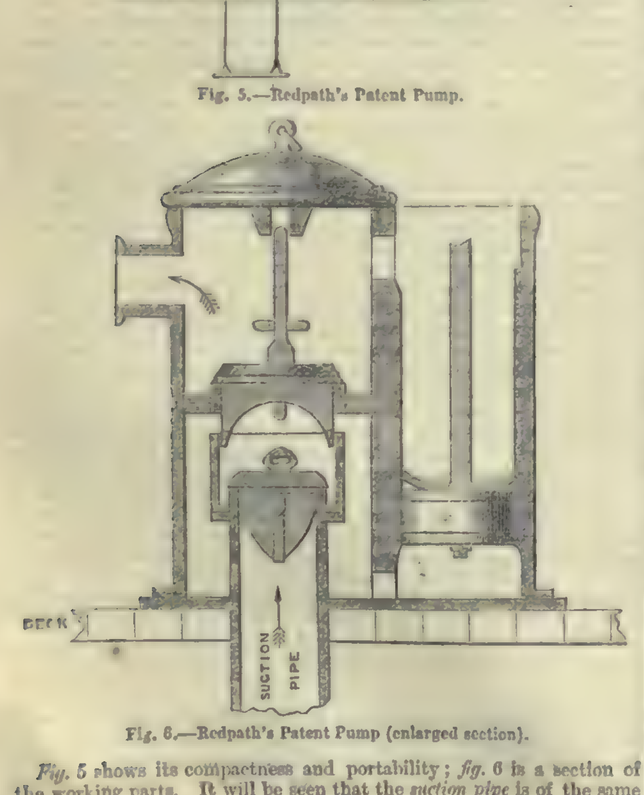

Fig. 6.—Redpath's Patent Pump (enlarged section).

Fig. 5 shows its compactness and portability; *fig.* 6 is a section of the working parts. It will be seen that the *suction pipe* is of the same area as the bottom valve, so that considerable friction and therefore labour are thus saved; and the bottom valve, like the upper valve, requires no fixing: both valves being made wholly of metal they *drop* into their places—it is therefore scarcely possible for them to get out of order.

The whole is exceedingly simple, and whereas at the trial in the Fisgard the other pumps occupied about seven minutes in taking apart and being replaced into working order; Redpath's was done in about half a minute (a valuable qualification in a leaky ship). This pump has no leather buckets nor bottom boxes, but the bottom *valve* is so placed that should any accumulation of sand, tar, oakum, chips, or shingle occur, if they are too large for the pumps to deliver, it is only the work of a few seconds to *lift* the valves in order to free them. Nearly 1000 of these pumps are afloat in British ships, and the simplicity of its action has obtained for it also a large sale in the American and other navies.

PUMPKIN is the vulgar name of the fruit of the *Cucurbita maxima*, a plant whose native country is not certainly known, but which is probably a variety of *C. pepo*, a species inhabiting the Levant. It is, as is well known, an annual plant, sending forth many long succulent angular rough shoots, bearing leaves and flowers something like those of the cucumber. Its fruit is often of enormous size, specimens having been produced in this country weighing 220 lbs., and in hotter countries they are still larger. This kind of fruit is however only furnished by the variety called the yellow Potiron; in other varieties it is much smaller. The seed of the pumpkin should be raised in a frame, in a garden-pot, after the same manner as the cucumber, and planted out upon a dunghill, or in any well-manured soil, as soon as the frosts are gone, beyond which it requires little or no care. The fruit, when ripe, is used for soup, or is baked with apples or pears as an ingredient in tarts. When young, it may also be boiled and brought to table like vegetable marrow.

PUN. A pun has been defined by Addison ('Spectator,' No. 61) to be "a conceit arising from the use of two words that agree in the sound but differ in the sense." Sometimes, however, the pun is effected by the employment of only one word, which is susceptible of a double application; as when one who had undertaken to pun upon any subject that should be given him, on being desired to make a pun on the king, answered that the king was no subject. Sometimes, too, the sound that is thus made to convey two ideas at once is not an entire word, but only a syllable. The definition, moreover, to be complete, ought to have explained in what the effect of the conceit consists. It appears to be, as we have just hinted, in the novelty and unexpectedness of the signification or application presented by the pun—a novelty which always at least produces surprise, and often the livelier titillation of a grotesque or otherwise ludicrous image.

A sketch of the history of puns has been given by Addison in a well-known paper in the 'Spectator' (No. 61), in which he traces the existence of the practice from the time of Aristotle downward. The figures of speech or turns of expression known among the Greeks by the names of the *paragramma* (παράγραμμα), and the *paronomasia* (παρωνομασία), the *antanaclasis* (ἀντανάκλασις), and the *plôke* (πλοκή), were often merely what we should now call puns. Addison observes that Aristotle, in the eleventh chapter of his 'Rhetoric,' describes different kinds of puns or paragrams, among the beauties of good writing, and produces instances of them out of some of the greatest authors in the Greek tongue. We may also refer to another very clever paper in the 'Guardian' (No. 36), attributed to a writer of the name of Birch, which contains what is called 'A Modest Apology for Punning.' In the introduction to this paper the distinction is happily enough drawn between the extemporaneous puns of conversation and the punning in deliberate and grave compositions, which in this country, in the early part of the 17th century, used to be reckoned eloquence and fine writing. "I look," says the author, "upon premeditated quibbles and puns committed to the press, as unpardonable crimes. There is as much difference betwixt these and the starts in common discourse as betwixt casual rencontres and murder with malice prepense."

PUNCH, the name of the principal character in a well-known puppet-show which is exhibited about the streets, and which appears to have originated in Italy. The name is a corruption of *Policinella*, the Neapolitan clown, who is generally the leading character in puppet-show performances. But the show itself, or rather the puppets, are styled by the Italians *Fantoccini*. Galiani, in his 'Vocabolario del Dialetto Napoletano,' ascribes the origin of *Policinella*, or rather *Polecenella*, as it is pronounced by the Neapolitans, to a company of strolling comedians, who, having met with a droll peasant named Puccio d'Aniello, at the town of Acerra, near Naples, engaged him to appear in his native character. By degrees personifications of the original Polecenella were multiplied all over the country. The character was made the medium of much witty satire, private and political, became the popular favourite with all Neapolitans, and thence spread elsewhere. It is noteworthy that the district in which Acerra is situated was remarkable in ancient times for that kind of dramatic wit and farcical humour which has made the reputation of the modern Polecenella. [ATELLANÆ FABULÆ.] Mr. Forsyth, indeed, thinks that the descent has been uninterrupted, and that the name has been derived from the nose, "a pulliceno pullicinello," a belief, he thinks, confirmed by an ancient bronze figure discovered in Rome, possessing the prominent feature which has ever been characteristic of Punch.

PUNCHING. [CHASING; MINT; RIVETING.]

PUNCTUATION is the art of dividing written or printed composition into sentences and clauses, by points or stops, so as to indicate the closer or more remote connection of the several parts. It serves to elucidate the sense, and thus also assists the delivery, since the latter must have reference to the grammatical construction.

The elements of a system of punctuation are discoverable in ancient times. Aristotle mentions the subject in his 'Rhetoric' (iii. 5); Jerome, in the 4th century, attended to the punctuation of the sacred books which he revised; about the middle of the 5th century, Euthalius published an edition of the four Gospels, and afterwards of the Acts, and of all the apostolic Epistles, in which he divided the New Testament into *stichoi* (στίχοι), or lines, regulated by the sense, so that each terminated where some pause was made in the reading; and in the Alexandrine manuscript, which may be referred to the 4th or 5th century, we find not only a break at the end of each paragraph, but stops inserted, though sparingly, in the body of the sentences.

The invention of the modern system of punctuation has been attributed to Aristophanes, a grammarian of Alexandria; but the subject was very imperfectly understood till the close of the 15th century, when the learned Venetian printers, the Manutii, increased the number of the signs, and established some fixed rules which have been so generally adopted, that we may regard them as the inventors of the present system.

The points used in English composition are:—

The comma, marked thus	,	The period, or full stop	.
The semicolon	;	The note of interrogation	?
The colon	:	The note of admiration	!

to which may be added the dash —, the apostrophe ', and the parenthesis ( ).

It is considered that the proper length of the pause at a comma is while we may count *one*; at a semicolon, *two*; at a colon, *three*; and at a period, *four*. But it will be easy to show that there is frequently a much greater separation of the sense, and that there ought therefore to be a longer pause at some commas than at others. Thus in the following sentence there should evidently be a longer pause after *instance*, than after *candour*, *fortitude*, *charity*, and *generosity*, though these words are all followed by the same mark of grammatical punctuation, namely the comma: "The qualities of candour, fortitude, charity, and generosity, for instance, are not in their own nature virtues; and if ever they deserve the title, it is owing only to justice, which impels and directs them."

The form and structure of sentences are so various, that it would be difficult, if not impossible, to lay down rules for punctuation which shall meet every case which can occur. The following may serve as a general guide.

I. The *comma* is used,—

1. To throw together such similar parts of speech as are joined in pairs by the conjunction *and*.

2. To separate the several members of a series, that is, a succession of similar words or members.

3. To separate from the rest of the sentence such clauses as are added by way of explication or illustration, or such as are really parenthetical, though they may not be so marked.

4. To separate from the rest of the sentence words in the vocative case.

5. In many cases to separate the relative and the antecedent.

6. To separate from the rest of the sentence such clauses as are introduced by a connective, conditional, or exceptive particle, or by an adverb of time or place; and to separate antithetical clauses, and such comparative clauses as are introduced by the adjectives *like*, *better*, by the conjunctions *as*, *so*, *than*, by the adverbs *how much*, *more*, *oftener*, *rather*, unless the comparative member at the end be short.

II. The *semicolon* is used when a longer pause is required than at a comma, but when the sense is imperfect, and needs some other member to render it complete. Or it is used for dividing a compound sentence into two or more parts, which are not so closely connected as those which are separated by commas only, nor yet so independent and perfect as those which admit a colon: thus—

"Life, with a swift though insensible course, glides away; and like a river which undermines its banks, gradually impairs our state."

"As there is a worldly happiness which God perceives to be only disguised misery; as there are worldly honours which in his estimation are a reproach; so there is a worldly wisdom which in his sight is foolishness."

III. The *colon* may be inserted—

1. When a member of a sentence is complete in itself, but is followed by some additional remark or illustration of the subject: thus—

'Do not flatter yourself with the idea of enjoying perfect happiness: there is no such thing in the world."

"Keep close to thy business: it will keep thee from wickedness, poverty, and shame."

2. When several semicolons have preceded, and when a longer pause is necessary in order to mark the connecting or concluding sentiment: thus—

"A divine legislator uttering his voice from heaven; an almighty governor stretching forth his arm to punish or reward; informing us of perpetual rest prepared hereafter for the righteous, and of indignation and wrath awaiting the wicked: these are the considerations which overawe the world, which support integrity, and which check guilt."

3. A colon is generally placed at the close of the words which introduce an example, a quotation, a saying, a speech, or a narrative: thus—

"The Earl of Chatham made an excellent speech, from which the following is a brief extract: 'I know that the conquest of British America is an impossibility.'"

IV. The *period* or full stop is placed at the end of a sentence, that is, at the end of such an assemblage of words as present a complete and independent sense: thus—

"Truth is the basis of every virtue."

"The Latin tongue is now called a dead language, because it is not spoken as the mother tongue of any nation."

In some sentences an additional clause is included, which does not modify the preceding: thus—

"The law of the Lord is perfect, converting the soul."

These are called *loose sentences*.

V. The *note of interrogation*, as its name implies, is placed at the end of every question.

The Spaniards place this mark also *at the beginning* of interrogative sentences; and it must be acknowledged that in some cases this is an advantage, as it suggests to the reader from the first the tones of voice which are suitable.

VI. The *note of exclamation* or *admiration* is placed at the end of such words or clauses as express any strong passion or emotion of the mind.

The *dash* should be used sparingly: it is introduced with propriety where a sentence or dialogue breaks off abruptly; where the sense is suspended, and continued after a short interruption; where a significant pause is required; where there is an unexpected turn in the sentiment, or a sort of epigrammatic point; when a sentence consists of several clauses which form the nominative to a verb following, or lead to a conclusion or inference, and it is desirable to assist the eye more readily than by semicolons; and in some cases to indicate an ellipsis.

The *apostrophe* shows the omission of a letter, as in *form'd*, *e'en*, *e'er*, used chiefly in poetry; and in the genitive case, as *man's*, *boys'*, both in prose and poetry.

The *parenthesis* marks a clause, which should contain some necessary information, or a useful remark, introduced into the body of a sentence *indirectly*, but which might be omitted without doing injury to the sense of the construction.

It has been remarked above, that one use of the points is as a guide to reading; but it must not be supposed that those which are usually inserted even in well punctuated books are sufficient for this purpose. But the pauses required in good and impressive reading or speaking belong to *elocution*, and will be found treated of under ORATORY.

PUNICIN. A non-azotised, bitter, uncrystallisable substance of unknown composition found in the bark of the *Punica granatum*.

PUNISHMENT. The verb *to punish* (whence the noun substantive *punishment*) is formed from the French *punir*, derived from the Latin *punire*, anciently *poenire*, which is connected with *poena* and the Greek ποίνη. Poine signified a pecuniary satisfaction for an offence, similar to the *wehrgeld* of the German codes: *poena* had doubtless originally a similar sense; but in the Latin classical writers its meaning is equivalent to that of our word *punishment*.

Punishment may be inflicted on men by a supernatural being or by men; and it may be inflicted on them either in the present life, or in the existence which commences after death. Punishment may likewise be inflicted by men on the more intelligent and useful species of animals, such as horses and dogs. In the following remarks, we confine ourselves to punishment inflicted by man on man.

The original idea of punishment was, pain inflicted on or endured by a person as a satisfaction or atonement by him for some offence which he had committed. (Grimm, 'Deutsche Rechtsalterthümer.') According to this conception of punishment, it appeared to be just that a person should suffer the same amount of pain which he had inflicted on others by his offence; and hence the origin of the retaliatory principle of punishment, or the *lex talionis*. This principle is of great antiquity, and is probably the earliest idea which all nations have formed concerning the nature of punishment. It occurs among the early Greeks, and was attributed by them to their mythical prince and judge of Hades, Rhadamanthys. They embodied it in the following proverbial verse:—

εἴ κε πάθοι τά κ' ἔρεξε, δίκη κ' ἰθεῖα γένοιτο.
(Aristot., 'Eth. Nic.,' v. 8.)

The *talio* was also recognised in the Twelve Tables of Rome ('Inst.,' iv. 4, § 7), and upon it was founded the well-known provision of the Mosaic law, "an eye for an eye, and a tooth for a tooth:" a maxim which is condemned by the Christian morality. (Matth., v. 38–40;

and Michaelis, 'Commentaries on the Laws of Moses,' vol. iii., art. 240–2.)

The infliction of pain for the purpose of exacting a satisfaction for an offence committed is *vengeance*, and punishment inflicted for this purpose is *vindictive*.

By degrees it was perceived that the infliction of pain for a vindictive purpose is not consistent with justice and utility, or with the spirit of the Christian ethics; and that the proper end of punishment is not to avenge past, but to prevent future offences. (Blackstone's 'Commentaries,' vol. iv.)

This end can only be attained by inflicting pain on persons who have committed the offences; and as this effect is also produced by vindictive punishment, vindictive punishment incidentally tends to deter from the commission of offences. Hence Lord Bacon justly calls revenge a sort of wild justice.

But inasmuch as the proper end of punishment is to deter from the commission of offences, punishment inflicted on the vindictive principle often fails to produce the desired purpose, and moreover often involves the infliction of an unnecessary amount of pain. Again, the degree of the punishment will often be placed too high, if regard is had merely to the suffering produced by the offence in the individual case, or to the moral turpitude implied by it, and not to the facility or difficulty of prevention, or the mischievousness of the class of offences. All punishment is an evil, though a necessary one. The pain produced by the offence is one evil; the pain produced by the punishment is an additional evil; though the latter is necessary, in order to prevent the recurrence of the offence. Consequently a penal system ought to aim at economising pain, by diffusing the largest amount of salutary terror, and thereby deterring as much as possible from crimes, at the smallest expense of punishments actually inflicted; or (as the idea is concisely expressed by Cicero), "ut metus ad omnes, pœna ad paucos, perveniret." ('Pro Cluentio,' c. 46.)

It follows from what has been said, that it is essential to a punishment to be *painful*. Accordingly, all the known punishments have involved the infliction of pain by different means, as death, mutilation of the body, flogging or beating, privation of bodily liberty by confinement of various sorts, banishment, forced labour, privation of civil rights, pecuniary fine. The punishment of death is called *capital* punishment: other punishments are sometimes known by the name of *secondary* punishments. Moreover, the pain ought to be sufficiently great to deter persons from committing the offence, and not greater than is necessary for this purpose.

A punishment ought further to be, as far as the necessary defects of police and judicial procedure will permit, *certain*; and also, as far as the differences of human natures and circumstances will permit, *equal*.

If a punishment be painful, and the pain be of the proper amount, and if it be likewise tolerably equal and certain, it will be a good punishment.

The qualities just enumerated are those which it is most important that a punishment should possess. But it is sometimes thought desirable that a punishment should possess other qualities than those which we have enumerated.

1. Since the time when it has been generally understood that punishment ought not to be inflicted on a vindictive principle, the deterring principle of punishment (which necessarily involves an infliction of pain) has been sometimes overlooked, and it has been thought that the end of punishment is the reformation of the person punished. This view of the nature of punishment is erroneous in excluding the exemplary character of punishment, and thus limiting its effects to the persons who have committed the offence, instead of comprehending the much larger number of persons who may commit it. The reformation of convicts who are suffering their punishment is an object which ought to enter into a good penal system; but it is of subordinate importance as compared with the effect of the punishment in deterring unconvicted persons from committing similar offences.

2. It is likewise sometimes thought that punishment is inflicted for the purpose of getting rid of offenders, or of rendering them physically incapable of repeating their offence. Death has often been inflicted for this purpose; and bodily disablements of different sorts have been inflicted for the same end; transportation has likewise been often recommended on the ground of its getting rid of convicts. This view of punishment errs in the same manner as that just examined; inasmuch as it is confined to the persons who have actually committed offences. If all offenders were removed to a place of reward, they would be got rid of, but not punished. The principle of getting rid of the offender, or his confinement, for the purpose of protecting society against the known dangerous tendencies of a person, is properly applicable in the case of madmen.

A detailed account of the punishments which have been used in different nations may be found in different works on antiquities and law books. See, for the Greeks, Wachsmuth's 'Greek Antiquities,' vol. ii.; Hermann's 'Greek Antiquities,' § 139; for the Romans, Haubold's 'Lineamenta,' § 147; for the ancient Germans and for Europe generally in the middle ages, Grimm's 'Deutsche Rechtsalterthümer,' b. v., ch. 3; for modern France, 'Le Code Pénal,' liv. 1; and for England, Blackstone's 'Commentaries,' vol. iv.

The *Secondary Punishments* inflicted in this country are noticed under CRIMES AND PUNISHMENTS and PENAL SERVITUDE.

An idle question is sometimes raised as to the right of a government to inflict death as a punishment for crimes, or, as it is also stated, as to the lawfulness of capital punishment. That a government has the power of inflicting capital punishment connot be doubted; and in order to determine whether that power is rightfully exercised, it is necessary to consider whether its infliction is, on the whole, beneficial to the community. The following considerations may serve to determine this question respecting any given class of crimes. Death is unquestionably the most formidable of all punishments; the common sense of mankind, and the experience of all ages and countries, bear evidence to the truth of this remark. Moreover, capital punishment effectually gets rid of the convict. On the other hand, capital punishment, from its severity and consequent formidableness, is likely to become unpopular; and hence, from the unwillingness of judges and juries to convict for capital offences, and of governments to carry capital sentences into effect, uncertain. Whenever the infliction of capital punishments becomes uncertain, their efficacy ceases, and they ought to be mitigated. An uncertain punishment is not feared, and consequently the pain caused by its actual infliction is wasted. Capital punishments ought therefore to be pronounced only for crimes which could not be effectually prevented by a secondary punishment, and for which they are actually inflicted with as much constancy as the necessary defects of judicial procedure will allow.

PUPIL, ARTIFICIAL. The operation of forming an artificial aperture in the iris is required in a variety of cases in which the passage of light through the natural pupil to the deeper seated parts of the eye is obstructed; and to meet the different exigencies of these several cases various operations have been suggested, each of which in its turn deserves to be preferred. The chief of these are—1, the tearing away a portion of the iris from its attachment to the ciliary ligament [EYE], a method which is however now very rarely employed; 2, the making a simple incision through some part of the iris, by the retraction of whose edges an elliptical or circular aperture is produced; 3, the making a portion of the iris protrude through an aperture in the cornea, and cutting it off. In whatever way the operation be performed, it is necessary to make the aperture in the iris as large as possible, that when it contracts in the process of cicatrisation, it may not be too small to permit the passage of a sufficient quantity of light for useful vision.

PURCHASE, corrupted from the Latin Perquisitio, is defined by Littleton (i. 12) to be "the possession of lands or tenements that a man hath by his deed or agreement, unto which possession he cometh not by title of descent from any of his ancestors, or of his cousins (consanguinei), but by his own deed;" and thus comprehends all the modes of acquiring property in land otherwise than by descent. [DESCENT; PROPERTY.]

PURGATION. [ORDEAL.]

PURGATORY ('a place of expiation,' from the Latin verb *purgare*, 'to cleanse') is the name given by Roman Catholics to an intermediate state of souls after death, and before the final judgment, during which they are supposed to expiate by certain punishments the guilt which they have incurred through life. Roman Catholic divines teach that it is only the souls of those who die in a state of repentance and in the communion of the church that are admitted into purgatory; those who die impenitent, or in a state of unbelief, are doomed to everlasting punishment. As for the duration of the term of expiation in purgatory, that is a matter which rests with divine justice, and varies according to the guilt of the parties, but Roman Catholics believe that the prayers of the living and other pious works may serve to shorten the term of souls in purgatory. This has given rise to the doctrine of indulgences, with which that of purgatory is closely connected. [INDULGENCE.] The Protestant and other churches which dissent from the church of Rome do not believe in purgatory. No mention of purgatory appears before the time of Augustine, who, in some of his works, speaks of it in terms not very explicit. The doctrine is said to have been first inculcated as a matter of belief by Gregory the Great, at the end of the 6th century.

PURITANS, a name first given in the reign of Queen Elizabeth to such clergymen of the Church of England as declined to subscribe to its liturgy, ceremonies, and discipline, according to the requirements of the bishops in their respective dioceses. Fuller assigns the origin of this name to the year 1564, and Strype to the year 1569; but it seems not very easy to ascertain the exact date when any such name might have been first used. The clergymen so called were advocates for a further reformation than the existing authorities deemed it proper to sanction; they desired a form of worship more simple and *pure* than they believed that to be of the church as then established. They were called Puritans probably out of derision, and the name was shortly applied to the laity as well as to the clergy. The Puritans were by other writers of the 17th century generally called non-conformists, a name first applied to men who objected to the clerical vestments about 1550. As Puritans they made a great figure in the Civil War against Charles I., but they very shortly separated into more definite sects, as Presbyterians, Baptists, &c. For a general history of the Puritans, the work of Neal, on the one hand, and, on the other hand, the works of Strype and Collier, may be consulted. On the political influence exercised by the Puritans, all histories of England contain detailed accounts. [Dissenters; Nonconformists.]

PURPLE OF CASSIUS. [Gold.]

PURPURIC ACID. [Uric Acid.]

PURPURIN. [Madder, Colouring matters of.]

PURREE. [Euxanthic Acid.]

PURREIC ACID. [Euxanthic Acid.]

PURRENONE. [Euxanthic Acid.]

PURSER. [Navy.]

PURVEYANCE (*purveance*, a providing), a prerogative formerly enjoyed by the king through the means of officers called purveyors, of purchasing provisions and other necessaries for the use of the royal household, and of employing horses and carriages in his service, in preference to all other persons, and without the consent of the owners. The parties whose property was thus taken were entitled to a recompense; but what they received was so inadequate, and so many abuses were committed under the pretext of purveyance, that it seems to have been always considered a most intolerable grievance. About forty statutes were passed upon the subject, many of them, like all the important early statutes, being a re-enactment of those preceding. Some of the most stringent occur in the 36th year of Edward III., and confining the exercise of it to the king and queen, (for it had frequently been asserted as their right by some of the great lords) provide that for the future "the heinous name of purveyor shall be changed into that of buyer;" forbid the use of force; and direct that where purveyors cannot agree upon the price, an appraisement shall be made, &c. &c. The provisions of these statutes appear to have wholly failed; and others were passed, but without effect. Several of the charges against Wolsey were the exercise of purveyance on his own behalf. (4 'Inst.' 93.)

In the time of Elizabeth, two attempts were made in the same year by the Commons to regulate the abuses of purveyance, at which the queen was extremely indignant. She seems to have employed this prerogative for the purpose of victualling her navy; but afterwards revoked the warrants, and designed to have taken away the commissions relating to the provision for her own household, some counties having agreed to furnish it at a certain rate, to get rid of the collectors—a kind of vermin which the queen called *harpies*. During the first parliament of James I., Bacon, on presenting a petition to the king, delivered his famous speech against purveyors, which forms a sort of compendium of the heavy charges made against them. Several negociations took place in that reign for the purchase of the prerogative of purveyance, but nothing was done. Under the commonwealth it fell into disuse, but was not formally abolished till after the restoration, by the statute 12 Ch. II., c. 24, the king receiving in lieu of it a certain amount payable on exciseable liquors. In the earlier periods of our history, purveyance was necessary for the support of the royal household; hence its continuance in spite of so many attempts to suppress it. Even after its final abolition several temporary statutes were passed, for its partial revival on the occasion of royal progresses. On behalf of the navy and ordnance, a statute to that effect occurs as late as 11 and 12 Will. 3. (Camden, 388; Bacon's 'Works,' vol. vi., p. 3, Montagu's edit.; Hume's 'Hist.'; 1 Bl. 'Com.', 287; 3 'Inst.', 82; 4 'Inst.', 273.)

PUS. [Abscess; Inflammation.]

PUTREFACTION. When nitrogenous organic matters are exposed to air and moisture at a moderate temperature, they begin to combine with oxygen, and are said to undergo decay, being resolved gradually into carbonic acid, water and ammonia, or nitric acid. If such decaying matters be wholly immersed in water, they continue the changes which had commenced in air, at the expense of the oxygen of the water, which unites with carbon, hydrogen, and nitrogen as before, whilst the hydrogen of the water also unites with another portion of the carbon, forming light carburetted hydrogen—a gas known to be evolved from stagnant pools, and the presence of which in such cases is always a test of putrefaction. [Eremacausis.]

PUTTY, the useful cement used by glaziers for fastening the glass in the frames of windows, is composed of linseed oil and whiting. The whiting should be well dried, and then pounded and sifted till it becomes a fine powder and is quite free from grit. The whiting, a little warm, should be gradually added to the oil, and well mixed by means of a piece of stick or a spatula. When it is sufficiently stiff, it should be well worked with the hand on a table, and afterwards beaten on a stone with a wooden mallet, till it becomes a soft, smooth, tenacious mass. Putty by exposure to the air gradually hardens till it becomes almost like stone. A ball of putty, when left some days, becomes somewhat hard, but may be easily softened by beating.

PUTTY POWDER is a pulverised oxide of tin, or of tin and lead, used in polishing. The metals are exposed to heat and to the admission of air in a furnace, or muffle of peculiar form; and the oxide is taken out in lumps about as hard as marble. The lumps are ground to powder under a runner, and the powder is sifted through lawn. The putty powder mostly used is an oxide of the mixed metal, or rather a mixture of two oxides, and is largely used as glass and marble polish, and as plate-powder. For the finer kinds of work, such as polishing lenses, the tin alone is used, without admixture with lead. The late Mr. Andrew Ross, the eminent optician, adopted a special mode, devised by himself, of making putty powder for polishing the exquisite lenses of his telescopes and microscopes. [Tin; Metatannic Acid.]

PUZZUOLANO. [Pozzuolano.]

PYÆMIA (pus in the blood), is a peculiar and dangerous state of the system, supposed to be produced by the introduction of pus into the blood. The symptoms connected with this state of the blood may occur in the course of other diseases, or they may come on without any previous attack of disease. The more characteristic symptoms are generally ushered in by more or less violent fits of shivering. When it is accompanied with any external suppurating surface, as is frequently the case, the discharge from this surface gradually dries up or becomes thinner and excessively fetid, and the wound assumes a flabby and unhealthy aspect. The patient becomes exceedingly languid and exhausted, and stupor or delirium comes on. The respiratory function is increased and the breath exhales a faint sickly odour. The lungs become congested, and the skin assumes gradually a yellowish tinge. Pains, with swelling, occur in the joints, and in the course of a little time effusion takes place in the synovial membrane and under the skin. The pulse is quick, tremulous, and rapid; the tongue, at first loaded with a yellowish fur, quickly becomes brown and dry, and the teeth and lips are covered with sordes. The abdomen becomes tender, and is frequently distended with flatus. The eye is dull, partial paralysis presents itself, the voice becomes feeble, and the patient sinks from the fourth to the tenth day from the first appearance of these symptoms.

After death the most conspicuous lesions are large accumulations of pus and puriform matter in the various parts of the body. These are found in the lungs, liver, spleen, brain, kidneys, heart, blood-vessels, pleura, joints, muscles, and the subcutaneous connective tissue. On examining the blood under the microscope, an increase in the white cells of the blood, which are not to be distinguished from pus-cells, has been observed. This, however, has not been observed in all cases; hence, perhaps, the impropriety of calling this disease by its present name.

The symptoms of this disease are generally the same as those which occur in inflammation of the veins or phlebitis. This state is again supposed to be identical with the disease occurring in puerperal women, and known by the name of phlegmasia dolens. [Puerperal Diseases; Veins, Diseases of.] The pathological state in which these symptoms come on has excited much discussion. Dr. Bennett gives the following:

1. That this condition is owing to an admixture of the blood with pus (pyohemia of Piorry), and that the pus corpuscles being larger than the coloured ones of blood, are arrested in the minute capillaries, and give rise to secondary abscesses.
2. That it is owing to the presence of any irritating body which cannot be eliminated from the economy, producing capillary phlebitis.
3. That it is dependent on a property possessed by pus of coagulating the blood.
4. That it is produced by the presence of a peculiar poison which contaminates the system.

The first view has been most generally held, but the fact that pus globules cannot be distinguished from the white cells of the blood would clearly indicate that they could not be retained in the capillaries as required by that theory. It is also found that in leucocythemia the blood is crowded with white cells without producing any of the above symptoms. Dr. Bennett also injected pus into the blood of an ass without producing any ill effects on the animal. These objections are also fatal to the second and third theories. The last view is that which is most consistent with the whole of the phenomena, and is alone applicable to those cases of pyæmia in which there is no wound or ulcerated surface, and no indication of the presence of pus cells in the blood. From the fact that this disease occurs where persons are exposed to poisonous exhalations from decomposing animal and vegetable matter from without, or to the absorption of decomposing animal secretions upon the body, it would appear that the blood becomes vitiated, and that the presence of pus cells in the blood, and depositions of pus in the various organs of the body, are but the results of this condition of the blood.

This disease is most frequently fatal, and each case requires to be treated according to the symptoms it presents. Local wounds must be attended to, and accumulations of pus should be removed by free incisions. The symptoms from the first indicate the necessity of stimulants, as wine and ammonia, and the introduction of nutritive and digestible food into the system. Quinine in large doses has been recommended.

PYIN. An albuminous substance contained in pus. Mulder considers it to be trioxyprotein.

PYRAMID (*πυραμίς*), a solid figure contained by a polygonal base and the triangles formed on the sides of the base by lines drawn from one point to the angles of the base. It is among plane solids what the cone is among curvilinear ones, and its solid content is one-third of that of a prism of the same base and altitude; that is, the number of square units in the base, multiplied by the number of linear units in the altitude, and the product divided by 3, gives the number of cubic units in the content.

The properties of a pyramid are important in the theory of Projections, particularly the following:—Every quadrangular pyramid (or pyramid with a quadrangular base) has one section, and one only, which is a parallelogram. To find it, let the vertex be V, and let opposite sides of the base meet in A and B. Then every plane parallel to AVB cuts the pyramid in a parallelogram, one of whose angles is equal to the angle AVB.

PYRAMID, the term applied to elevated mounds of stone or brickwork of the geometrical shape of that name, the most remarkable of which are those in the plain of Gizeh, which were considered one of the seven wonders of the ancient world. The origin of the name is involved in much obscurity; but it appears, like obelisk, to be a Greek term, the hieroglyphic word for pyramid being *pa abmer*, *ben ben*, or *ber b r*; the Coptic *piharam*, and Arabic *el haram*, being derived from the Greek. These pyramids are sloped or symmetrical mounds placed over the graves or chambers of the sepulchres made for the monarchs and other great personages of the earliest Egyptian dynasties, commencing with the 3rd and ending with the 12th, after which their use was abandoned in Egypt. The pyramids lying in a vast plain or cemetery, extending from 29° to 30′ N. lat., for between 60 and 70 miles, are supposed to be about 69 in number. They are all constructed in a uniform manner. A rectangular sepulchral chamber was first hollowed in the rock, with a passage of sufficient dimensions to admit the sarcophagus, communicating with the surface. Over this was at once erected a cubical course of masonry, which served for the nucleus of the pyramid. If the king died during the year, the masonry was covered with a polished casing in shape of a small pyramid; if the monarch survived, another course of masonry was added to the height of the nucleus, and the length of the lower stage or base increased by courses of stone on each side. Additions on the same plan continued to be made as long as the king lived, fresh courses being added from year to year. When the monarch died this ceased; the pyramid was cased by filling up the angles of the masonry with smaller stones, placing oblong blocks one upon another, so as to make a series of steps from the top to the base, and then bevelling off all these stones, commencing from the top downwards, at a uniform angle. A smooth surface was given to each side of the pyramid, rendering it a perfect triangle, while, owing to each stone overlapping the other, no vertical joint was left. Some differences are observable as to the manner in which the internal walls were either vertical or inclined; but the general principle is the same in all, and the mode of finishing the pyramid casings corresponds with the description of Herodotus (II. cxxv.). The means by which the stones were raised is not known; but the discovery of hemispherical holes about 8 inches in diameter, that look polished by the turning of a heavy body, have suggested the use of *derricks*, or similar machines—the employment of scaffolding for the purpose being impossible. All the pyramids are placed with their sides facing the four cardinal points of the compass, and their entrances are on the north side, somewhere about the centre. Extraordinary precautions were taken to prevent access to the sepulchral chambers; the passages, made exceedingly narrow, were closed by great blocks of stone or granite portcullises, which closed the passages before the apartment; and the entrance was not placed in the centre of the elevated masonry, where it could have been easily seen, but in the plain below.

The first group of pyramids is that of Memphis, the three principal of which are echelloned on an elevated plateau, 120 stadia from Memphis and 45 from the Nile. The largest of these- said by Herodotus to have been built by Cheops, by Diodorus attributed to Chembes or Chabryes, and by Manetho and Eratosthenes to Suphis or Saophis I.—formerly had a base 764 ft. square, which has been diminished, by the continual spoliation of the sides for material to build the city of Cairo, to 746 ft. Its ancient height, judging by the casing stones discovered by Colonel Howard Vyse, was 480 feet; its present is only 450. The angle of its inclination is 51° 50′. It is built upon the rock, which has been cut down at the sides to obtain a level platform; and its entrance, which lies 24 ft. 6 in. east of the centre of the north side, is 3 ft. 5½ in. broad by 3 ft. 11 in. high, with an incline of 26° 41′. This passage descends to the original sepulchral chamber of the pyramid, commonly called the subterraneous apartment, with a distance of 320 ft. 10 in. This apartment, which measures 46 ft. long by 27 ft. 1 in. wide, with a height of 11 ft. 6 in., has at its south end a horizontal passage of 52 ft. 9 in. long by 2 ft. 7 in. broad, and 2 ft. 8 in. high, leading south, apparently a continuation of the works in this direction for the purpose of forming a second sepulchral chamber for holding the furniture of the mummy; but the work was abandoned in this direction, because the prolonged life of the monarch caused the mouth of the passage in the rock to be covered by the masonry added to the body of the pyramid. At the distance of 63 ft. 2 in. from the entrance another passage of the same size was constructed at an angle of 26° 18′, and ran for 124 ft. 4 in. so slippery that the ascent was effected by small holes cut for the purpose, and then became a horizontal passage parallel to the plane of site of the pyramid, 109 ft. 11 in. long. Part of this passage is rather broader than the rest, and leads to a chamber commonly called the Queen's, having a groined roof, measuring 17 ft. by 18 ft. 9 in., and 20 ft. 3 in. high, having a recess at the east side, and placed nearly in the centre of the pyramid, at a distance of 67 ft. 4 in. from the floor or plane of site of the pyramid. This chamber was evidently made for the reception of the sarcophagus, but was subsequently abandoned, and the ascending passage continued on a larger scale with granite blocks 28 ft. high and 150 ft. 10 in. long, with a short horizontal passage leading to the upper or so-called King's chamber. In this short passage was a portcullis 12 ft. 5 in. high, to defend any entrance into the chamber. The King's chamber had a flat roof, and measures 17 ft. 1 in. by 34 ft. 3 in., with a height of 19 ft. 1 in., and the north side is more than 16 ft. 3 in. south of the pyramid, probably because the monarch was expected to survive so long as to admit of sufficient masonry being added to enable it to be placed there. As the heat and confinement of this chamber appears to have been stifling, two air-channels, one 9½ in. by 9 in., the other 9⅛ in by 8⅞ in., ran from the chamber to the north and south faces of the pyramid: these, when opened by Mr. Perring in 1837, restored the ventilation to the chamber. In the chamber itself is a sarcophagus of red granite, 7 ft. 6½ in. long by 3 ft. 3 in. broad, and 3 ft. 5 in. high without its cover, entirely plain, and neither ornamented with sculpture or inscriptions. This no doubt anciently contained a wooden coffin, in which was deposited the body of the founder; but both have disappeared long since, when the pyramid was opened and plundered. The King's chamber is surmounted by five other small chambers placed above, the uppermost having a pointed roof formed by stones placed *en décharge*. The object of these chambers appears to have been to lighten the roof of the apartment, which is flat, from the weight of the superincumbent mass. These chambers are from 37 ft. to 38 ft. 4 in. long, and from 16 ft. 4 in. to 20 ft. 6 in. wide. The height varies from 1 ft. 4 in. to 8 ft. 7 in., and they rise for 69 ft. 3 in. from the roof of the great chamber. The first of these nearest that point was discovered by Davison in 1764, the others by Colonel Howard Vyse in 1837, who named them Wellington, Nelson, Arbuthnot, and Campbell chambers; but they are generally called the chambers of construction, as showing the purpose for which they were made.

The opening of these chambers solved the enigma of the pyramid; their floors and roofs were made by blocks of red or syenitic granite from the quarries of Assouan, but the sides were partly formed by blocks of a hard calcareous stone, brought from the quarries of Mokattam and Tourah. While yet in the quarries the workmen had scrawled upon them in large linear hieroglyphics, in a red colour, the names and royal titles of two kings, accompanied by other words. Those in the so-called Nelson chamber, nearest the king's chamber, had only the standard name of Khufu, or Cheops; those in the Arbuthnot chamber the standard name, titles, and cartouche of Khnum Khufu; and those in the uppermost chamber, the titles and cartouche of Khufu, or Cheops, and hieroglyphs with numerals. Although an attempt has been made to show that these are two different monarchs, yet the fact of both having the same Horus or standard name at this epoch, shows that both names belong only to one monarch, the Khufu of the hieroglyphs and Cheops of Herodotus, whose body anciently reposed in the sarcophagus of the sepulchral chamber beneath. These quarry marks were placed in all sorts of ways in the chamber, and sometimes had been cut short by the sawing of the blocks of stone, showing that they were inscribed while the material was in the quarries. At the junction of the two inclined passages is the so-called well, consisting of a shaft 2 ft. 4 in. square, descending perpendicularly for 26 ft. 1 in., then 32 ft. 5 in. to a recess called the grotto, and finally for 183 ft. to the subterraneous apartment. It was cut through the masonry after it had been constructed, and therefore evidently did not form part of the original design, and is supposed to have been made for the workmen to descend after they had closed up the passage from the upper end of it. The base of this pyramid is about 137 ft. above the level of the inundation of the Nile; it contains at present 82,111,000 cubic feet of masonry, and anciently about 7,000,000 more, and the weight is calculated as 6,316,000 tons, covering at present 12 a. 3 r. 3 p. As it exists at present, stripped of its casing, there are 203 steps; they decrease, but not regularly, from the bottom to the top from 4 ft. 10 in. to 2 ft. 2 in., the stones being 9 ft. long, and 6½ ft. broad. The ascent is fatiguing, but not attended with danger, the summit having been often reached by ladies. The horizontal lines of the platforms are fitted with the greatest nicety, and joined by a cement of lime without sand. Some of the casing-stones at the base were discovered by Colonel Howard Vyse, and gave the angle of inclination. This pyramid is supposed to have been open at the Roman times, and traces of Latin inscriptions are said to have been found in the passages, as well as Cufic inscribed during the rule of the Arab conquerors of Egypt.

According to Herodotus the great pyramid was built by Cheops, who closed the temples, and stopped the sacrifices, and made a conscription of the people to build this monument by bringing the stone from the Tourah quarries; gangs of 100,000 men were relieved every three months; ten years were employed for the causeway, 3,000 ft. long, 60 ft. wide, 48 ft. high, which had a hieroglyphical inscription; the subterraneous chamber, he states, was in an island made by a canal from the Nile; twenty more years were consumed for the masonry. It was constructed like steps, and the stones were raised from layer to layer by machines. He describes the manner of facing the pyramid from the top, and gives an account of a hieroglyphical inscription, recording 1600 talents of silver spent for the radishes and onions supplied to the workmen. Cheops reigned 50 years. Diodorus calls this monarch Chembes. At the time of Pliny the pyramids were then ascended, although the casing of the great pyramid is said to have remained till the Christian era. The pyramids in recent times have been visited and described by travellers since Belonius, A.D. 1553.

The second pyramid, called the pyramid of Cephren, was built by that monarch, who reigned, according to Herodotus, 56, and Manetho, 66, and the Canon of Turin gives the length of his life as 95 years. The base of this pyramid is elevated 33 ft. 2 in. above that of the great pyramid, or nearly 172 feet above the level of the high Nile. The ancient base measured 707 ft. 9 in., but it is now reduced to 690 ft. 9 in.; the height was formerly 454 ft. 3 in., but is now 447 ft. 6 in., the inclined was 572 ft. 6 in., now diminished by 9 ft.; the angle is 52° 20′, the apex is 9 ft. square, the casing from the top 130 ft. to 150 ft. It is placed in an excavation made in the solid rock. Belzoni, after great exertions, succeeded in opening this pyramid, which has two inclined entrances, one in the masonry of the pyramid itself 37 ft. 8 in. above the base, at an angle of 25° 55′, and 104 ft. 10 in. long; the lower one 96 ft. 4 in. long, at an angle of 21° 40′, placed before the base, both leading to a sepulchral chamber of 46 ft. 2 in. by 16 ft. 2 in., and 19 ft. 3 in. high, with a roof of the same shape as the pyramid, in which was found a granite sarcophagus 8 ft. 7 in. long, 3 ft. 6·5 in. wide, and 3 ft. high, close to the S. and W. sides of the chamber, on which was found a Cufic inscription, recording the visit of the Caliph Othman, and the opening of the pyramid by him in A.D. 1196-7. Some bones of a bull, but no human remains were found in this pyramid. The two lower tiers of the exterior and entrance have fresh coatings of granite, the casing is hard stone of Mokattam. The masonry is formed of blocks and rubble.

The third pyramid was built by Menkare, the Mycerinus of Herodotus, Mencheres of Manetho, and Moscheris of Eratosthenes, the third king of the 4th dynasty. A level for the site was obtained by a substruction more than 10 ft. deep, laid to the west, consisting of two tiers of immense blocks. The entrance of this pyramid was discovered by Colonel Howard Vyse, in July 1837, at a height of 13 feet above the base, and measuring 3 ft. 5½ in. by 3 ft 11½ in. The passage appears to have been forced by the Mamelukes. The base measured 354 ft. 6 in., the perpendicular height 218 ft., its angle was 51°. The passage entered at 26° 2′, ran for 104 feet, and led to an ante-room of 10 ft. 5 in. by 12 ft. and 7 ft. high, covered with white plaster worked in compartments, passing thence to three portcullises, a passage of 41 ft. 3 in. long, 3 ft. 5½ in. broad, and 5 ft. 10 in. high, led thence, at an angle of 4°, to the so-called large apartment, measuring 46 ft. 3 in. long by 12 ft. 7 in. broad, about 15 ft. high, in which was a place for a sarcophagus. A passage of 4 ft. 9 in. high thence descended for 30 ft. to a portcullis which closed the sepulchral chamber of 21 ft. 8 in. by 8 ft. 7 in., and 11 ft. 3 in. high, lined with granite, containing a sarcophagus of whinstone, of 8 ft. long by 3 ft. 1 in. broad, and 2 ft. 11 in. high, ornamented with plain architectural ornaments similar to those seen in tombs of the 4th dynasty. A room 17 ft. 6 in. long by 6 ft. 3 in. broad, and 6 ft. 7 in. high, containing niches, was reached by a series of 7 steps. The large apartment had an ascending passage similar to the first, of 80 ft. 4 in. in length by 3 ft. 5½ in. broad, and almost 4 ft. high.

The sarcophagus in the sepulchral chamber was subsequently removed by Colonel H. Vyse, and sent to the British Museum, but lost at sea off Carthagena; fragments of the lid were found in the entrance of the passage to the large apartment, and close to it portions of a mummy case of cedar, of the usual shape, inscribed with the name of the king Menkare, and a prayer to the goddess Nu, and part of a body with a woollen garment, supposed by some to be the body of the monarch, by others that of an Arab. The casing of this pyramid has been nearly all removed; according to Herodotus, it extended half way up of Ethiopian stone, but the greatest height of the black granite is now 36 ft. 9 in. on the west side; according to Diodorus there were only 15 layers of granite. The name of its builder, according to the same, was inscribed on its north side. According to Manetho, Mencheres reigned 63 years. It is evident that, on account of the increased length of reign, an important alteration took place in the construction of this pyramid, the increasing masonry having extended beyond the mouth of the first or upper passage, rendering necessary the construction of the second inclined passage and the present sepulchral chamber, in place of the large apartment originally destined for that purpose, the old red granite sarcophagus having been broken in pieces for the purpose of removal, and a new sarcophagus made for the lower chamber. The chiselling of the upper passage, which is from the outside, and that of the lower inclined passage, which is from the inside, show that this passage was worked after the completion of the masonry. The third pyramid is better constructed than the others.

The former height of the fourth pyramid of Gizeh, the central, south of the third, was 69 ft. 6 in., the length of the base on the rock, 102 ft. 6 in.; it had an inclined passage of 27 ft. leading to an ante-room, and another 11 ft. 8 in. long, leading at an angle of 27° to a small sepulchral chamber, in which was an empty granite sarcophagus 6 ft. 8 in. long; in it was found the cartouche of *Kamenka*, or Mycerinus, and it was supposed to have contained the wife or daughter of that monarch. The fifth, or eastern pyramid, south of the third, formerly had a square base, 145 ft. 9 in., a height of 83 ft. 4 in., an inclined passage of 27° 12′, of 86 ft. 9 in., and a horizontal one of 4 ft., leading to an apartment 25 ft. by 10 ft. 5 in., containing a sarcophagus of granite above 8 ft. long; part of the 112th chapter of the Koran was found to have been formerly scrawled in it by some Arab visitant. The sixth, or western pyramid, south of the third, is 102 ft. 6 in. square at base, 69 ft. 6 in. high, with a passage of 30′ running 47 ft. 9 in., with an ante-room and sepulchral chamber. The seventh pyramid, north-east of the great pyramid, was formerly 111 ft. high, and 172 ft. 6 in. square, with an entrance passage of 55 ft. 3 in. long, inclined 33° 35′, leading to an ante-room and sepulchral chamber, without any sarcophagus. The eighth, central, east of great pyramid, of nearly the same dimensions, had had an entrance passage 37 ft. long, inclined 34° 5′, leading to an ante-room and sepulchral chamber. The ninth, south-east of the great pyramid, completing the Gizeh group, measures only 101 ft. 9 in. on a base 160 ft. square, with a passage of 53 ft., inclined 28°, to a sepulchral chamber. The entrances of all these pyramids were placed in front of the north face, generally at a little distance from the base.

The two largest pyramids were considered by the ancients one of the marvels of the world, and to be, as they actually are, sepulchres; but many absurd notions have been put forth by moderns as to their object, which has been supposed to have been to protect Memphis from the encroachments of sands, or imitation of Hindu edifices, or to square the circle, or vast reservoirs to purify the waters of the Nile, the burial place of Apis, or the granaries of Joseph. The best received hypothesis was, that the pyramids were for astronomical observation, and that the pole star was seen from the inclined passage, but it has been proved by Sir J. Herschel, that the pole star, α Draconis, of the age of Cheops, could never have been seen from the inclined passage. It is, however, generally agreed that the pyramids of this group are all of the age of the 4th dynasty, older than 2000 years B.C.

At Abou Roash, five miles N.W. of Gizeh, is a ruined pyramid of stone 320 ft. square at the base, without its casing, with a passage of 160 ft. at 22° 35′ inclination, leading to a sepulchral chamber 40 ft. by 15 ft., with chambers of construction; red illegible quarry marks were found in this pyramid. Another at Zowyet el Arrian, made of limestone from the neighbouring hills, is so rude in construction and destroyed as to have the appearance of a circular hill about 300 ft. broad, 61 ft. high above the rock. That of Reegah, situated near a deserted village of that name, about three-quarters of a mile N.W. of pyramid of Abooseer, composed of finer masonry cased with granite, rose at an angle of 75° 20′ with an upper part of Mokattam stone at 52°, and 123 ft. 4 in. square. Some sculptured stone, found N.E., had the names of Usren-Ra, king of the 3rd dynasty. At Abooseer are the remains of five pyramids—the Northern, cased with granite and Tourah limestone, had a base of 257 ft., reduced now to 216 ft., and rose 162 ft. 9 in., now reduced to 118 ft., at 51° 42′ 35″: it had a passage of 27° 5′ inclination, with an apartment in the centre with a destroyed sarcophagus of black basalt, and the name of Ra-sahu or Sahu-ra, king of the 3rd dynasty, was found in this pyramid. The middle pyramid, of rather larger dimensions, contained the name of the monarch Ra-Usr, of the 3rd dynasty. The great pyramid had been cased with granite. Its original base appears to have been 359 ft. 9 in.; now it is 325 ft., and it rose 237 ft. 10 in. high, now only 164 ft.; layers of split reeds painted red were found on the roof of the passage. The quarry marks contained the name and titles of a functionary. The small pyramid has only a base of 54 ft. 6 in., and was anciently only 78 ft. square. At Sakkara are eleven pyramids all built of stone, approached by inclined causeways from the plains below, and much decayed, except the large step-formed pyramid and that to the N.E. In the second pyramid remains of a plain basalt sarcophagus were found. The third step-shaped or great pyramid had an apartment covered with timbers, furnished with a hidden chamber. Its old base had been 351 ft. 2 in. by 393 ft. 11 in.; it is now 196 ft. 6 in. high. The doorway or entrance was encrusted with small coloured porcelain tiles worked into an inscription containing the name and title of the monarch Ra-nub-tam or probably the Chnonbos Gneuros of Eratosthenes. The fifth was entirely built of Tourah stone. The inscriptions in the third pyramid show that it was made for a high officer of state. At Dashour are five pyramids—three of stone and two of brick. The northern brick pyramid, supposed to be that of the Asychis of Herodotus, whose inscriptions boasted it was as superior to the stone pyramids as Jupiter to the other gods, formerly 218 ft. and now 90 ft. high, had a base of 350 ft. at an inclination of 51° 20′ 25″. This pyramid was anciently cased with stone, and had a portico of the same material, a portion of which was found, as also the end of a royal name resembling that of a king of the 12th dynasty. The south brick pyramid, much destroyed, is made of bricks mixed with straw and rubbish; it was cased with Mokattam stone, and the south stone one had an inscription with the name of a functionary. Two ruined stone pyramids are at Lisht; another, at Meydoum, called the false pyramid, which has not been opened, is supposed to belong to the 6th dynasty; that of Illahoun, also made of brick and stone walls; that of Howara, also of brick, has been cased with stone, has no inscription, but has been attributed to the 1st dynasty, whose 4th king Venephes or Venephres is said to have erected a pyramid at Kokome; those of Biahmoo, at Medinat El Fayoum, two in number, appear to have been the sepulchres of Amenemha IV., and Sebeknefru or Scemiophris, placed in the lake Mœris, near the Labyrinth, in the Arsinoite nome at Crocodilopolis. According to some these pyramids consist of the cores of the ancient monuments or pedestals of the statues of the kings. They are 23 ft. high, slope 64°, and stand on a layer of Nile mud. A ruined pyramid exists at El Kufa. At Thebes are some small pyramids of sun-dried bricks, the central chambers of which have vaulted roofs, supposed to be of the 16th century B.C. One of these at the Drah-Aboo-Negger, not facing the cardinal points, is entered by a passage leading to a chamber at the bottom of which is a tablet representing the king Enentef IV. of the 11th dynasty, followed by four dogs with their names. It is to this pyramid and the adjoining tombs that the Abbott papyrus refers. [Papyrus.]

The principal pyramids in Nubia are those of Beg e Rauie, about 17° N. lat., called by Cailliaud Assur, and Hoskins Begromi, which lie in three groups arranged in a crescent shape, and are the sepulchres of the monarchs of Meroe. They do not face the cardinal points, but the propylæa which are united to the pyramids all face the east, and the sepulchral chambers which are constructed in the masonry lie to the west. The inner walls of the sepulchral temples are ornamented with Osiris and other Egyptian deities, and the names and legends of the monarchs for whom they were made, one of whom had assumed the prænomen of Sesortesen I., but many of the names and inscriptions cannot be deciphered. The art is of a late period, but the number of kings show a long duration of empire. One of these pyramids had been encased and enlarged at a later period, and in another, Ferlini, in 1834, found a collection of solid gold rings, a bronze vase and other objects walled up. Another group of about one hundred and twenty lies at El Gues N. of Gebel Barkal, and at Nourri, 18° N. lat., another group of about twenty-five, the graves of the Æthiopian monarchs, whose capital was Mount Barkal, the ancient Napata, of which Tahraka was the most renowned monarch. The largest pyramid contains within it another of a different date, stone, and architecture. The base is about 155 ft., and the height about 104 ft. Other groups are at Tanqassi, Kurru, and Zuma.

Buildings of this shape are not confined to the valley of the Nile: the Birs Nimrud, of Belus, supposed to be the Tower of Babel, but now known to be a temple built by Nebuchadnezzar to the Seven Planets, in form of a step-shaped pyramid of different stages of appropriately coloured bricks 235 ft. high, with a perimeter of 2286 ft. The Mujellibe, also of pyramidal shape, is another edifice of brick-work erected by the same monarch; it is 140 ft. high, 600 ft. on the N., 657 on the S., 546 on the E., and 558 ft. on the W. side, and has a hollow shaft 60 ft. square. Xenophon, in his account of the retreat of the 10,000, also mentions a stone pyramid which he saw near the Tigris, about 45 miles S. of Mosul, about 200 ft. high. The tomb of Sardanapalus, at Tarsus, also appears to have been of pyramidal shape, and the mausoleum at Halicarnassus terminated in a step-shaped pyramid of 24 steps, rising 42 ft. 6 in., surmounted by a colossal quadriga. The idea seems borrowed from the Egyptians, with whom the Carians entertained at an early period political relations. Similar tombs, consisting of pyramids, supported on cellæ and columns or pilasters, have been found at Mylasa in Caria, at Oôrân near Ben Izli in Phrygia, at Celenderis in Cilicia, and elsewhere.

At Rome, within the walls of Aurelian, is a small pyramid 120 ft. high, and 95 ft. diameter, of marble face, formed of hewn stone upon a pavement of travertine, erected 20 or 30 years B.C. The door is on the N. side, and inside is a small sepulchral chamber with obliterated paintings on the walls and roof. It was erected in honour of C. Cestius, one of the seven marshals, *Epulones*, who furnished the banquets of the gods, according to the directions of his will by his executor M. Agrippa. There is an inscription on the front and back of the monument recording the name and title of the deceased, and that the work was begun and ended by Pontius and Pothas in 360 days — the Roman lunar year. It is generally known as the pyramid of Cestius, and was evidently imitated from the Egyptian.

There are some temples of pyramidal form at Benares, and other places in the East Indies, which are said to be copies of the sacred mount *Mene*, and are called *Meru Sringas*, or "Peaks of Meru." Pyramidal structures called *Leen tan*, representing the mountain of Yu, and used for sacrifice, exist at Pih-king, and have several stages ascended by flights of steps. Pyramidal temples have also been found at Suka in Java.

The Mexican pyramids called *Teocallis*, meaning "House of God," or "Temple," consist of pyramidal mounds of earth or stone, terraced, and mounted by steps, having on them the statues or altar of the god to whom they were dedicated, and where their bloody human sacrifices were performed. [Mexican Architecture.]

Pyramidal structures called *morais*, of large size, are found in the Polynesian islands: a stone one at Atehuru, 270 ft. long, 94 ft. broad at base, and 50 ft. high, with a flat top reached by a flight of steps, the lowest 6 ft. high; the whole was cased with coral and basalt; another at Maeva was 120 ft. square. These structures were used as places of worship and burial. Easter Isle abounds in these *morais*. Colossal statues were often erected on the summits.

The pyramidal form in connection with sacred and sepulchral edifices appears to be distributed all over the world, and is nothing more than a geometrical mound; the facility of forming it, and the grand simplicity as well as the solidity and pleasing proportions of the figure, having caused it to be selected as best suited for primæval architecture.

PYREN ($C_{30}H_{12}$?). A crystalline substance procured from gas-tar. It is insoluble in water, but crystallises in small rhombic laminæ in alcohol. It is insipid and inodorous, slightly soluble in alcohol and in ether. It melts at about 350° Fahr., and concretes on cooling into a crystalline mass. A stronger heat volatilises it without alteration. Sulphuric acid carbonises it. It much resembles paranaphthalin.

PYRIDINE ($C_{10}H_5N$). A volatile organic base found in bone-oil. In its properties it greatly resembles picoline. It yields the following derivatives:—

Chloroplatinate of pyridine . .	$C_{10}H_5N, HCl + PtCl_2$
Platinopyridine	$C_{10}H_3Pt''N$
Platosopyridine	$C_{10}H_4PtN$
Iodide of ethyl-pyridine . . .	$C_{10}H_5(C_4H_5)NI$

PYRITES. [Metals; *Iron, Bisulphate of.*]

PYROBENZOLIN. Synonymous with Lophine.

PYROCATECHIN. [Phenylic Group.]

PYROCITRIC ACID. [Citric Acid.]

PYROGALLIC ACID. ($C_{12}H_6O_6$). If the dry extract of nut-galls be heated to 356° Fahr. for 10 or 12 hours, a beautiful white crystalline substance sublimes, which is pyrogallic acid: 100 parts of the dry extract yield about 5 parts of the sublimed acid. Pyrogallic acid is soluble in 2¼ times its weight of cold water, and much less soluble in alcohol and ether. It does not redden litmus paper. Rendered alkaline with potash or soda, it rapidly absorbs oxygen, and assumes a blood-red colour. It is employed in eudiometry for the estimation of oxygen, and in photography for the development of collodion pictures.

PYROGUAIACIC ACID. [Guaiacyl.]

PYROINULIN. [Inulin.]

PYROLEIC ACID. [Sebacic Acid.]

PYROLICHENIN. A substance obtained from the *Variolaria amara.* In order to procure it the powder of the lichen is to be treated with alcohol, and the solution evaporated to the consistence of a syrup. The pyrolichenin then crystallises, and after being washed with a solution of carbonate of potash it is to be dissolved in and crystallised from alcohol.

Its properties are:—It forms colourless inodorous crystals unalterable in the air, inodorous, and of a bitter taste. It fuses below 212°, and concretes on cooling. It is insoluble in cold water, and slightly soluble in boiling water, and nothing is deposited from it on cooling. It is very soluble in alcohol, ether, bisulphide of carbon, and oils, both volatile and fixed. The alcoholic solution has an acid reaction, and, like the solution in acetic acid, and also in concentrated sulphuric acid, it is precipitated by water. It is not decomposed by the nitric, hydrochloric, or phosphoric acids.

It combines with ammonia, and forms yellow brilliant crystals, which effloresce in dry air. They are insipid, and dissolve readily in alcohol and the caustic alkalies. Solution of potash dissolves pyrolichenin with a wine-red colour, which gradually becomes brown. Acids precipitate from it a bitter reddish-brown substance. When decomposed by heat it yields no ammonia; and when heated in the air it burns with a bright sooty flame, which is violet-coloured on the edges. Its composition is not known: it is stated to possess antifebrile properties.

PYROLIGNEOUS ACID. [Acetic Acid.]

PYROLITHOFELLIC ACID. [Lithofellic Acid.]

PYROLIVILIC ACID. [Olivile.]

PYROLIZARIC ACID. [Naphthalic Group.]

PYROMARIC ACID. [Turpentine.]

PYROMECONIC ACID. [Meconic Acid.]

PYROMELLIC ACID ($C_{20}H_6O_{16}$). A crystalline organic acid, obtained by distilling mellic acid:—

$$\underbrace{3C_8H_2O_8}_{\text{Mellic acid.}} \quad = \quad \underbrace{4CO_2}_{\text{Carbonic acid.}} \quad + \quad \underbrace{C_{20}H_6O_{16}}_{\text{Pyromellic acid.}}$$

PYROMETER (literally "fire-measurer," from πῦρ, "fire," and μέτρον, "a measure"). No fluid has hitherto been found applicable to the construction of thermometers capable of indicating higher temperatures than that of boiling mercury (about 660° Fahr.). The term pyrometer was first employed by Muschenbroek to designate an instrument invented by him for measuring the effects produced in the dimensions of solid bodies by the application of heat; but the signification of the term has since been extended so as to include those instruments the object of which is to measure all gradations of temperature above those which can be indicated by the mercurial thermometer.

Muschenbroek's pyrometer consisted of a metallic bar, about six inches in length, one extremity of which was fixed, while the other was left free to advance as the metal elongated from the effect of the flames of several spirit-lamps placed beneath, which at each experiment were charged with the same quantity of highly rectified spirit of wine. The advance of the moveable extremity gave motion to a pinion and wheel, the latter of which drove an index over a graduated circle, each degree of which corresponded to a linear expansion of 12,500th of an inch. The instrument, as it was originally constructed, is described in the second part of Muschenbroek's translation of the 'Saggi di Naturali Esperienze fatte nell' Academia del Cimento,' Leyden, 1731; and as improved by Desaguliers (who substituted fine cords and friction-rollers for the wheel and pinion), in his 'Experimental Philosophy,' vol. i.

To Muschenbroek's pyrometer succeeded those of Ellicott (described in the 'Phil. Trans.' for 1736 and 1751), Graham ('Phil. Trans.,' 1754), Smeaton, Ferguson ('Lectures'), &c., which, like those that have since been constructed, with few exceptions, down to the present time, evince but little originality in the principle upon which they rest. A bar of metal is in most cases subjected to the direct action of flame, or immersed in a fluid of convenient temperature. The minute resulting expansion is multiplied, and thereby rendered appreciable by the intervention of a succession of levers or a system of wheels and pulleys. Supposing this intervening machinery to perform with theoretical accuracy, and that the same quantity of heat is successively communicated to different substances, the indications of such an instrument would give the relative expansions of those substances under the same circumstances. But where wheels, pinions, levers, &c., are employed, there must be considerable liability to error, arising from flexure, obliquity of action, and other causes, the magnitude of which it would be difficult to estimate, and which, even if it be supposed small in the first instance, will be magnified almost in the same proportion as the delicacy of the instrument is increased. Moreover the substance itself, if its nature be such as to be softened by heat, is very liable at high temperatures to undergo compression in giving motion to the machinery. Even, therefore, as measures of expansion they cannot be considered as deserving of much confidence. A similar remark is applicable, though in a less degree, to the contrivance employed by Lavoisier and Laplace, in which the expansion of the metal deflected a telescope from the position that it had at the commencement of the experiment, and the absolute expansion was deduced from the extent of this deflexion, which was read off upon a graduated scale placed at a considerable distance in front of the telescope. A description of the apparatus employed is given in Biot's 'Physique Expérimentale,' tome i., and a table of the expansions of the several substances experimented on between the temperatures of 32° and 212° Fahr. Troughton, in 1794, constructed an instrument which bore some resemblance to the preceding, the principal difference consisting in the employment of a spirit-level, the deviations of which from the horizontal determined the expansion of the metal.

The 'Phil. Trans.' for 1777 contain a description of the method employed by De Luc in the construction of his compensating pendulums, in order to determine the length of one metal whose expansion is equal to a given length of another metal. For this purpose he suspended the bar of known length from an arm projecting horizontally from an upright deal plank. To the lower extremity of this bar was adjusted a small horizontal platform, upon which a bar of the other metal rested in a vertical position. Upon raising the temperatures of both bars, every point on the surface of the second bar would obviously become subjected to two motions tending to move it in opposite directions: it would be depressed by the expansion of the first bar, and elevated by the expansion of the second. One point would therefore remain stationary, and this point, being ascertained by raising or lowering a microscope adjusted to the edge of the plank, determined the portion of the second bar, measured from its lower extremity, whose expansion was equal to the whole of the first bar.

The rods employed by Borda in measuring the base-line of the great French Survey consisted of a rule of brass laid upon a somewhat longer rule of platinum and attached at one extremity. The portion of the platinum rule not covered by the one of brass was divided into millionths of the entire length of the rule, and further subdivided by means of a vernier and microscope adjusted to the extremity of the brass rule. The value of each of these divisions having been previously ascertained by first surrounding the compound rule with melting ice, and then immersing it in boiling water, it was only necessary to observe the indications of the vernier in order to apply the requisite correction for reducing the length of the rod to the standard temperature.

For low temperatures, the contrivance of Ramsden, described in the 'Phil. Trans.' for 1785, and employed by General Roy in determining the expansion of the rods used in measuring the base on Hounslow Heath for the Trigonometrical Survey, was perhaps unexceptionable. The rod was immersed in a trough of water, and over each extremity was placed a microscope, to which a slow motion could be given in the direction of the length of the rod by means of a fine micrometer screw. The lines of collimation of the microscopes being thereby adjusted at the commencement of the experiment so as to coincide accurately with two points near the extremities of the rod, the temperature of the water was gradually raised till a thermometer placed in the trough indicated an advance of 10°, 20°, 30°, or any required number of degrees. The consequent elongation of the rod destroyed the coincidence of its extremities with the lines of collimation of the microscopes, which was re-established by turning the micrometer screws, and carefully noting the number of turns and fraction of a turn necessary for that purpose; when, the value in parts of an inch of each turn being previously known, a direct measure of the expansion was obtained, free from the errors of a system of levers or of a train of wheels and pinions.

The property of alumina whereby it undergoes a diminution of bulk when heated, was employed by Wedgwood as a measure of high temperatures. His pyrometer consisted of cylinders of fine white clay, and an apparatus for accurately measuring their length. This apparatus consisted of a metallic plate, upon which were fixed two brass rules slightly inclined to each other. The rules used by Wedgwood were 24 inches long, and divided into 240 equal parts. The distance between the rules at one extremity was 3-10ths and at the other 5-10ths of an inch; consequently the difference between their distances at any two consecutive divisions was the 1200th part of an inch. But it is obvious that these numbers are quite arbitrary, and that by increasing the length of the rules and diminishing their inclination, the difference between their distances at any two consecutive divisions may be made as small as we please. The clay cylinders were first baked at a red heat, estimated at 947° Fahr., and then reduced to exactly 5-10ths of an inch in length, so as to fit the first division of the scale. When afterwards exposed to a greater heat, they underwent contraction, and the amount of this contraction was determined by observing the division of the scale corresponding to their diminished length. If we then assume, with Wedgwood, that the contraction is proportional to the temperature at which it took place, the latter will likewise be determined; but independently of the difficulty of procuring pieces of clay of uniform composition, from which it resulted that two cylinders of equal length when exposed to the same heat seldom underwent the same degree of contraction, it has been found that the duration of the experiment has considerable influence upon the contraction, the longer continuance of a low temperature producing the same contraction as a higher degree of heat continued for a shorter time. As a measure of temperature, therefore, this method cannot be relied on, though as a direct measure of expansion we doubt if it has been surpassed either in the simplicity of its principle or in the minuteness of the indications of which it is susceptible. A description of the instrument, and of the experiments made with it, will be found in the 'Phil. Trans.' of 1782, 1784, and 1786.

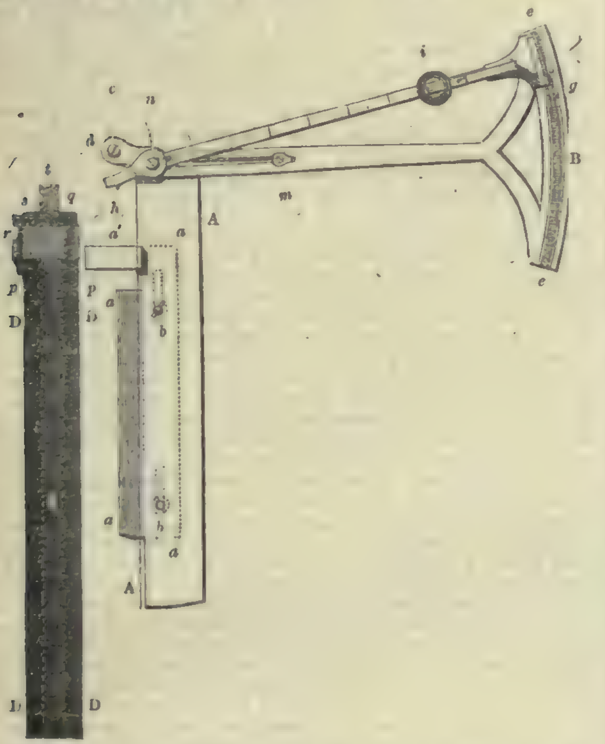
A pyrometer was constructed by Achard similar in form and principle to the common thermometer, but intended to indicate much higher degrees of heat. It consisted of a bulb and graduated tube of semi-transparent porcelain highly baked, and containing a very fusible alloy, composed of bismuth, lead, and tin, which became liquid at about 212°, and indicated higher temperatures by its expansion, which was visible through the semi-transparent tube.

Dulong and Petit employed a very direct mode of measuring the absolute, not linear, expansions of various substances. By observing the difference of altitude at which mercury of different temperatures stood in the two arms of an inverted glass siphon, they determined the absolute expansion of the mercury, and by comparing this with the apparent expansion of mercury in a glass tube, they deduced the absolute expansion of the glass. A cylinder of the metal whose expansion was sought was then placed within a glass tube, closed at one extremity and terminating at the other in a capillary opening, and the rest of the tube occupied with mercury. Upon the whole being heated, a portion of the mercury was expelled equal to the excess of the absolute expansions of the mercury and metal above that of the glass; and as the expansions of the mercury and glass were previously known, the weight of the expelled mercury determined the expansion of the metal.

Sir David Brewster has proposed to measure expansions by the number and intensity of the polarized tints produced by the inflexion of a plate of glass against which the expanding substance is made to press. (Brewster's 'Cyclopædia,' articles 'Pyrometer' and 'Optics.')

Guyton's pyrometer, which was exhibited before the National Institute in 1803, and described in the 'Annales de Chimie,' xlvi., p. 276, and in Nicholson's 'Philosophical Journal,' vi., p. 89, consisted of a bar of platinum nearly 2 inches in length, placed in a groove of porcelain. One extremity of the bar rested against the solid end of the groove, while the other pressed upon the short arm of a lever, the longer arm of which carried a vernier over a graduated circular arc. The whole was constructed of platinum, and a spring was made to press upon the vernier to prevent its displacement while in the act of withdrawing the instrument from the furnace. The indications of the vernier at the commencement and termination of the experiment were the data from which the expansion was subsequently computed. "The defect of this instrument," observes Mr. Daniell, "arose from the nature of platinum, which at a red heat becomes soft and ductile, so that the lever would be liable to bend, and thereby frustrate the experiment; and this is supposed to have been the reason why the inventor never extended his experiments to temperatures higher than that of the melting point of antimony."

As early as 1821, Professor Daniell had invented an instrument which, he states, "afforded correct determinations connected in an unexceptionable manner with the scale of the mercurial thermometer;" but it was only suited to the experimental furnace of the chemist, so that, he continues, "the great desideratum still remained of a pyrometer, which might be universally applied to the higher degrees of heat, as the thermometer had long been to the lower, and which, in addition to its use in delicate researches, might effect for the potter, the smelter, the enameller, and others, in the routine of their business, what the latter daily performs for the brewer, the distiller, the sugar-refiner, and the chemist." The annexed diagram represents the second pyrometer invented by Mr. Daniell, for which the Rumford medal was awarded to him by the Royal Society. An account of it is given in the 'Phil. Trans.' for 1830-31.



It consists of two distinct parts, the register and the scale. The register is a solid bar of black-lead earthenware, D D D D, eight inches long and seven-tenths of an inch wide and thick, cut out of a common black-lead crucible. In this a hole is drilled three-tenths of an inch in diameter, and seven inches and a half in depth. At *p p* the upper end of this bar, and on one of its sides about six-tenths of an inch in length of its substance, are cut away to the depth of half the diameter of the bore. When a bar of any metal six inches and a half long is dropped into this cavity, it rests against its solid end; and a cylindrical piece of porcelain, *q*, about one inch and a half long, called the index, is placed on the top of it, which, projecting into and beyond the open part, is firmly confined to its place by a strap of platinum, *r*, which passing round the black-lead bar and over the piece of porcelain, is made to press upon the latter with any required degree of tension by means of a small wedge *s* of porcelain inserted between the bar and the strap. When the register is exposed to the heat of a furnace, it is evident that, the expansion of the metallic bar exceeding that of the black-lead, the porcelain index will be forced forward; and when the register is afterwards cooled, the tension of the strap will retain the index at the point of greatest elongation.

The object of the scale is the accurate measurement of the distance through which the index has advanced. It consists of a frame, *a a a a*, composed of two rectangular plates of brass joined at right angles by their edges, and fitting square upon two sides of the register. At one extremity of this frame is a small plate of brass, *a'*, which, when the two former plates are applied to the register, is brought down upon the shoulder formed by cutting away the black-lead at *p*, and the whole may be thus firmly adjusted, when required, to the black-lead bar by three planes of contact. To the outside of this frame is firmly attached, by means of the screws *b b*, a brass plate A A, the extremity of which, *d*, projects so that a point, *c*, near to it may be immediately opposite to the cavity in the black-lead bar when the latter is adjusted to the frame. About *c* as a centre, turns an arm *d n* B slightly bent at *n*, carrying at its extremity a graduated circular arc *e e*. The radius of this arc is five inches, and its moveable centre *n* is distant from the fixed centre *c* exactly half an inch. About *n* turns a straight and lighter arm, *h g*, five inches and a half in length, the distance from *h* to *n* being half an inch. The extremity, *g*, of this arm carries a vernier, by which the divisions of the graduated arc are subdivided into minutes, and also an eye-glass, *i*, to assist the reading. The other extremity terminates in a steel point, *h*, or, as the instrument is now constructed, a knife-edge, which, when the register is adjusted to the frame, is inserted in a small cavity, *t*, formed for its reception at the extremity of the porcelain index. A small steel spring let into the larger arm at *m* is made to press upon the lighter arm, whereby the latter has a constant tendency to move towards the commencement of the graduation.

When the instrument is used, the metallic bar to be experimented on is placed in the cavity of the register, and the index pressed down upon it and firmly fixed in its place by the platinum strap and porcelain wedge. The scale is then applied by carefully adjusting the frame to the register and fixing it by pressing *a'* upon the shoulder. Holding the whole together steadily in the left hand, the lighter arm is so placed that the steel point *h* may rest upon the edge of the index, against which it will be pressed by the spring; then by slightly turning the larger arm, the point will move along the surface of the index till it drops into the cavity *t*. The indications of the vernier being then read off, the register is detached from the scale, placed in the furnace, and after it is removed and cooled, it is again applied to the scale in the same manner as before, and the second indication of the vernier noted. From the two readings of the vernier may be deduced the excess of the expansion of the metallic bar above that of the black-lead, though a correct formula for this purpose has not, to the writer's knowledge, been hitherto given.

The one employed by Mr. Daniell, though probably sufficiently correct for all practical purposes, gives the expansions one per cent., too great without exception, and in many cases much more, so that more than the first *significant* figure can seldom be depended upon in those published by him in the 'Phil. Trans.' of 1830-31. The error thus introduced is perhaps within the limits of the error to which the instrument itself is liable; but should this not be the case, it might be desirable to employ the correct formula, for which reason we subjoin its investigation.

Let $c n \mathrm{B}$, $h n g$, represent the positions of the two arms of the scale relative to the register, before the expansion has taken place, and $c n' \mathrm{B}'$, $h' n' g'$, their positions after the expansion; h and h' the two positions of the steel point, the line joining which passes through the fixed centre c; e and e' the two positions of the zero of the graduated arc. Put the angle $c n \mathrm{B} = c n' \mathrm{B}' = \alpha$; $e n \mathrm{B} = e' n' \mathrm{B}' = \beta$; $e n g$ (the first reading of the vernier) $= \phi$; $e' n' g'$ (the second reading) $= \phi'$; also $c n = c n' = n h = n' h' = r$; and $h h' = \epsilon$, the excess of the expansion of the metal above that of the black lead: then

$$\epsilon = \frac{\sin h n n' - \sin h' n' n}{\sin h' h n - \sin h h' n'} \times \text{chord } n n';$$

$$\begin{aligned}\text{But}\quad h n n' &= 270^\circ - \alpha + \beta - \tfrac{1}{4}(3\phi + \phi');\\ h' n' n &= -90^\circ + \alpha - \beta + \tfrac{1}{4}(3\phi' + \phi);\\ h' h n &= \tfrac{1}{2}(\alpha - \beta + \phi);\\ h h' n' &= 180^\circ - \tfrac{1}{2}(\alpha - \beta + \phi');\\ \text{chord } n n' &= 2 r \sin \tfrac{1}{2}(\phi' - \phi);\\ &= \sin \tfrac{1}{2}(\phi' - \phi), \text{ since } r = \tfrac{1}{2}.\end{aligned}$$

∴ substituting and reducing by means of the formula

$$\sin \mathrm{A} - \sin \mathrm{B} = 2 \cos \frac{\mathrm{A} + \mathrm{B}}{2} \sin \frac{\mathrm{A} - \mathrm{B}}{2}, \text{ there results}$$

$$\epsilon = 2 \sin \tfrac{1}{4}(\phi' - \phi) \sin \left\{ \tfrac{1}{2}(\alpha - \beta) - \tfrac{1}{4}(\phi' + \phi) \right\}$$

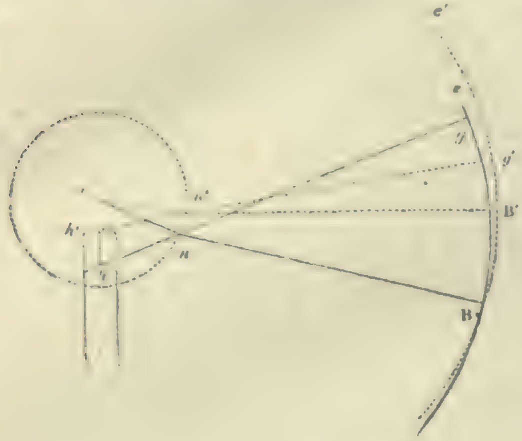
If $\alpha = 180^\circ$ and $\beta = 15^\circ$, as is nearly the case, this reduces to

$$\epsilon = 2 \sin \tfrac{1}{4}(\phi' - \phi) \cos \left\{ 7^\circ\, 30' + \tfrac{1}{4}(\phi' + \phi) \right\},$$

where the unit of measurement is one inch.

The formula used by Mr. Daniell is $\epsilon = \sin \frac{1}{2}(\phi' - \phi)$, or its equivalent, since $\phi' - \phi$ is generally a small angle, $\epsilon = 2 \sin \frac{1}{4}(\phi' - \phi)$; from which it appears that all the expansions given by him should be diminished in the ratio of $1 : \cos \left\{ 7^\circ\, 30' + \frac{1}{4}(\phi' + \phi) \right\}$; but as he has recorded only the difference $\phi' - \phi$ of the readings of the vernier, and not the readings themselves, this correction can only be made by a repetition of the whole of the experiments. The error is inconsiderable so long as ϕ and ϕ' are both small, but it increases with the increase of either of those angles.

The excess of the expansion of the metal above that of the black-lead being thus obtained, and increased by the expansion of the latter (the determination of which is less direct and conclusive), the expansion of the metal becomes known. In order that the instrument may then be employed as a measure of temperature as well as of expansion, the doubtful assumption is introduced that equal increments of length are the effects of equal increments of temperature, and thence, having determined the expansion between any two known points on the thermometric scale, say the temperatures of melting ice and boiling mercury, a mere proportion will of course give the temperature at which any other observed expansion took place.



A paper was communicated to the Royal Society by the late Mr. Prinsep, the assay-master of the Mint at Benares, "On the Measurement of High Temperatures,' and published in their 'Transactions' for 1828. "The fusing-points of pure metals," observes that gentleman, "are determinate and unchangeable; they also comprehend nearly the whole range of temperature; the unoxidable or noble metals alone embrace a range from the low melting-point of silver to the high ignition of platina. There are, it is true, only three fixed points in this scale, but as many intermediate links may be made as are required, by alloying the three metals together in different proportions. When such a series has been once prepared, the heat of any furnace may be expressed by the alloy of least fusibility which it is capable of melting." As the melting-points of silver and gold are comparatively near to each other, Mr. Prinsep assumed only ten intermediate gradations of heat, the lowest of which corresponded to the fusing-point of pure silver, and the others to the fusing-points of silver alloyed with 10, 20, 30, &c. per cent. of gold. From the melting-point of gold to that of platina, he assumed one hundred gradations of heat, which were the melting-points of pure gold and of gold alloyed with 1, 2, 3, &c., per cent. of platina. Among the advantages of this mode of identifying temperatures are; — the smallness of the requisite apparatus, nothing more being needed than a small cupel, containing in separate cells eight or ten pyrometic alloys, each of the size of a pin's head; the indestructibility of the specimens, since those melted in one experiment need only to be flattened under a hammer, when they will be again ready for use; and the facility of notation, since two letters and the decimal of alloy will express the maximum heat: thus S ·3 G expresses the temperature of the fusing-point of silver when alloyed with gold in the proportion of 7 to 3; and G ·23 P expresses the fusing-point of gold when alloyed with platina in the proportion of 77 to 23.

Several suggestions have been made for employing the expansion of air, on the principle of the differential thermometer, as a measure of high temperatures. It is proposed that one-half of the instrument be composed of platinum, so as to fit it for exposure to a great heat, and the other part of glass. The suggestion, we believe, is originally due to Mr. Schmidt (Nicholson's 'Journal,' xi.); but was brought forward under another form by Mr. Nicholas Mill, in the 'Monthly Medico-Chirurgical Review and Chemico-Philosophical Magazine,' vol. i., Lond., 1824; again by Dr. Ure, in his 'Dictionary of Chemistry;' and lastly by Mr. Prinsep. The instrument, we believe, has been constructed upon each of the plans proposed. That of Mr. Prinsep appears the most complete (see a drawing of the apparatus in full operation at page 87 of his Memoir above referred to), and was employed by him to connect the fusing-points of his alloys with the thermometric scale; but the principle upon which they all rest involves the assumption that the increase of temperature is proportional to the expansion of the air.

A valuable table of the expansions of different substances collected from various sources by Mr. Francis Baily, is given in the first volume of the 'Transactions of the Astronomical Society,' p. 416.

The above admirable article well nigh exhausts the subject of the pyrometer. Since the date of its publication in the 'Penny Cyclopædia,' very little has been done towards perfecting this instrument. We may, however, briefly notice a few points of interest in connection therewith.

Mr. Prinsep's method of alloys was tested some years ago in the laboratory of the Sèvres porcelain manufactory, with a view to determine the temperatures of the kilns used in baking porcelain. It was found necessary to expel silver from the brief list, on account of its absorbing oxygen when in a state of fusion and spitting it out again when cooling. Alloys of platinum and gold in various proportions were tried, but it was found that similar alloys did not always melt at the same moment, although apparently placed under precisely the same circumstances. It was also found that the same bead of alloy could not be used more than once, on account of some molecular change produced by the heat which led to an alteration in the fusing point. It was however determined that the highest temperature attained in the kiln at Sèvres was represented by the alloy $\left.\begin{matrix}\text{P. }53\\\text{G. }47\end{matrix}\right\}100$, when a well fused button was formed; whereas when 54 parts of platinum were used, only a softening of the alloy was perceived. M. Brongniart, 'Traité des Arts Céramiques,' remarks that if it be possible to determine exactly and promptly the moment when complete fusion takes place in these alloys, they will afford comparable measures of high temperatures; but not a method fit to be employed habitually in industrial operations.

So long since as the year 1805, M. Brongniart constructed a pyrometer for measuring the comparatively moderate heat of the glass oven, or muffle furnace at Sèvres, by means of the dilatation of a bar of silver. The readiness with which this metal can be obtained pure renders the results of two instruments comparable, although it is not adapted to measure very high temperatures. The bar of silver is two decimetres in length, and it is placed among the articles which are being fired, resting in a groove of hard porcelain, one end of which is turned up to serve as a fixed point to the further end of the bar, while the near end presses against a porcelain rod, which gives motion to a needle over a graduated arc. For further particulars we must refer to M. Brongniart's work, above cited.

In the Great Exhibition of 1851, Mr. Ericsson exhibited in the United States department an instrument intended to supply what we think is still a desideratum, namely, a good pyrometer for the useful arts. In this instrument temperatures were indicated by the tension of a permanent volume of air, or of nitrogen gas, which was measured by the reading of a column of mercury under a vacuum. For the particulars of this instrument we must refer to the Jury Report.

In the 'Transactions of the Royal Society of Edinburgh,' vol. xiii. will be found an account of an ingenious pyrometer by Mr. Adie, for measuring the expansion of different kinds of stone. We have not space to describe the instrument, but we may mention one curious effect, namely, that there was an increase in length in white Sicilian marble, every time its temperature was raised.

We may also refer to M. Pouillet's method of measuring directly the linear expansion of solids applicable to very high temperatures. It consists of a solid plate of metal on which is placed a radius turning on a centre, and traversing a graduated arc, the divisions of which are read off by a microscope. The radius carries a telescope of short focus, fixed at right angles to its direction, while a similar telescope is fixed to the plate itself, allowing the radius to traverse under it. The bar which is the subject of experiment is placed in a copper trough, furnished with parallel plates of glass, through which its ends can be seen. Now if one extremity of the bar be kept opposite the fixed telescope, while the moveable telescope is directed to the other extremity at the commencement of the observation, any expansion of the bar caused by raising its temperature may be estimated by the arc through which the radius must be turned in order to bring the moveable telescope to bear on the other extremity in its new position, the distance of the radius from the bar being accurately known. For very high temperatures the bar may be placed in a furnace, and when raised to the required temperature, apertures may be opened in the furnace walls, so as to give a view of the ends of the bar, and allow its expansion to be measured as before. By means of this apparatus an expansion in the bar of $\frac{1}{1000}$th millimetres or about $\frac{1}{30000}$th inch can be appreciated.

We may also refer to an ingenious contrivance adopted by General Colby in measuring the base line of Loch Foyle, for the Ordnance Survey of Ireland. It consisted of a compound bar of iron and brass so arranged that their different powers of expansion and contraction should preserve exactly the same distance between two points at the extremities of the bars, instead of allowing for the change in length according to the observed temperature. The two bars, one of iron the other of brass, each 10 feet long, were placed parallel to each other and riveted together in the centre. It was ascertained by experiment that the iron and brass bars expanded and contracted by varying temperatures in the proportion of three to five. Across each extremity therefore of these combined bars was fixed a tongue of iron, with a minute dot of platinum so placed, that under every degree of expansion and contraction of the rods the dots at each end always remain at the constant distance of 10 feet.

PYROMORINTANNIC ACID. [OXYPHENIC ACID.]

PYROMUCIC ACID. [MUCIC ACID.]

PYROPECTIC ACID. [PECTIC ACID.]

PYROPHORUS. [LEAD: *Tartrate of.*]

PYROPHOSPHORIC ACID. [PHOSPHORUS.]

PYROPIN. A red albuminous substance found in elephants' teeth.

PYROSIS, or WATER BRASH, is a disorder of the stomach, attended with the vomiting or eructation of a thin watery liquid.

This liquid is usually insipid and tasteless, but sometimes it has an acid taste. Cullen speaks of this disease as a common complaint in Scotland, and it has been attributed to the employment of farinaceous food, especially oatmeal, as an article of diet. It usually comes on in the early part of the day when the stomach is empty. The first symptom of it is a pain at the pit of the stomach, with a sense of constriction as if the stomach were drawn towards the back. The pain is increased by raising the body into an erect posture, and therefore the body is bent forward. The pain is often very severe, and after continuing for some time it brings on an eructation of a thin watery fluid in considerable quantity. These symptoms often occur without any other indications of dyspepsia, although they are not unfrequently accompanied with other indications of derangement of the digestive organs. It sometimes occurs with violent neuralgic pains of the stomach, constituting gastrodynia. Pyrosis also accompanies organic disease of the stomach.

In the treatment of this disease, the preparations of opium with bismuth and astringents, as kino and catechu, are found to be of most service; at the same time the bowels require to be kept open, which should be done by means of castor oil, confection of senna, or other mild purgative.

PYROXAM. [XYLOIDIN.]

PYROXANTHIN ($C_{20}H_8O_4$?). A beautiful yellow crystalline product of the action of alkalies upon wood-tar. Concentrated sulphuric and hydrochloric acids dissolve it with the production of a dark red colour.

PYROXYLIC SPIRIT. [METHYL, *hydrated oxide of.*]

PYROXYLIN. [GUN COTTON.]

PYRROL. A volatile oily alkaloid, discovered by Runge in coal-tar. Its composition is not known. Anderson regards it as a mixture of several substances.

PYTHIAN GAMES (*Pythia*, or *Pythici Ludi*), one of the four great national festivals of the Greeks, were celebrated near Delphi, in honour of Apollo, originally every ninth year, and afterwards every fifth year, in the autumn of the third year of each Olympiad, in the second or third month of the year, according to Clinton. Corsini and others, followed by Boeckh, place them in the spring, in the month Munychion, the tenth of the year. Their origin is assigned by some to Amphictyon, the son of Deucalion, or to the Amphictyonic council; by others to Agamemnon; by Pausanias to Diomed; by Strabo to the Delphians, after the Crissæan war; but most commonly to Apollo, after he had vanquished the serpent Python. (Ovid, 'Met.', i. 445.) There is an account that the gods and heroes contended in the first celebration of these games, when Castor conquered in the horse-race, Pollux in boxing, Calais in the foot-race, Zetes in fighting in armour, Peleus in throwing the quoit, Telamon in wrestling, and Heracles in the Pancratium. But the fact seems to be, as stated by Pausanias (x. 7, 2) and Strabo (ix., p. 421), that the contest was originally in music: the songs (πυθικοὶ νόμοι) were in honour of Apollo, celebrating his victory over the Python; and the instrument used was the lyre. In the third year of the 48th Olympiad (B.C. 586), at the close of the Cirrhæan war, the Amphictyons added a contest on the flute, which was afterwards discontinued, as the music of the flute was considered too mournful for a joyous festival. In the same year the Amphictyons also introduced athletic contests and races (but not with four-horsed chariots), the foot-race being confined to boys; and the games, according to Strabo, were then for the first time called *Pythia*; at all events the subsequent Pythia are computed from this year by Pausanias and the Parian marble, though the scholiast on Pindar, and Eusebius, date them from the second celebration, in Ol. 49, 3: Boeckh and Clinton prefer the former date. Chariot-races were added in the time of Cleisthenes, the tyrant of Sicyon. Statues, pictures, and other works of art, were also exhibited at the Pythia, and prizes adjudged to the most successful artists. The prize in the Pythian games was originally of silver or gold, or something else of intrinsic value; but afterwards a crown of laurel, or (according to Ovid, 'Met.', i. 449-50) at first, of the bay-oak or beech-tree (*æsculus*), for which the laurel was afterwards substituted. The ceremonies observed at these games in common with the three other great festivals, are described under OLYMPIAN GAMES. The attendance at the games was very great, as all Greeks were permitted to be present at them. The Pythia are believed not to have been entirely discontinued till about the same time as the Olympian games, 394 A.D.

(Pausanias, x. 7; Strabo, ix.; Potter's *Archæologia Græca*, vol. i.; Wachsmuth, *Hellenische Alterthumsk.*; Clinton, *Fasti Hellen.*; Krause, *Die Pythien.*)

PYX, or PIX, the box or casket in which is kept the consecrated host reserved for the sick in the Romish church. Among the ancients the pyxis (πύξις) was the casket in which ladies kept their jewels and other ornaments. It was itself often made of the most costly materials, and enriched with sculpture or with gems. There can be little doubt that it was from the ancient jewel-box that the mediæval ecclesiastics derived the name of their pyx, and perhaps also the idea of its enrichment. At any rate the pyxes of mediæval date which still remain are among the costliest examples of the art-workmanship of the middle ages. Some good ones are in the South Kensington Museum; others are preserved among the plate of some of the colleges of Oxford and Cambridge, but the finest are in the treasuries of continental churches. The pyx was placed upon the altar under a covering or canopy, and at its elevation the sacring bell was rung. Among the French especially the pyx seems to have been not unfrequently in the form of a dove, enamelled and enriched with gems. The term pyx was sometimes applied to the casket in which relics were kept. [RELIQUARY.]

PYXIS NAUTICA (the mariner's compass), a southern constellation of Lacaille, placed in Argo. It contains no stars of conspicuous magnitude.

POLARIZATION OF LIGHT is a peculiar affection of that agent to which the term has been applied because a ray of polarized light possesses properties which have relation to two opposite directions in a plane perpendicular to the ray. We shall first describe some of the circumstances under which polarized light is formed, and the characters by which it is recognised as polarized, and afterwards explain the view which is taken of its nature in the theory of undulations, the only theory which has given a simple and intelligible account of its complicated phenomena.

The affection of light now known as polarization was discovered by Huygens in the course of his researches on the laws of double refraction in Iceland spar. A rhomb of this crystal has the property of dividing a ray of light incident upon it into two rays, which are propagated in different directions within the crystal, and produce each an emergent ray parallel to the incident, so that the two emergent rays are separated laterally by a space proportional, *cæteris paribus*, to the thickness of the rhomb, the direction of separation (supposing for simplicity the ray to be incident perpendicularly) being that of a line bisecting an obtuse angle of the rhombic face, and the intensity of the two emergent rays being under ordinary circumstances the same. Such a rhomb gives two images, of equal intensity, of an object on which it is placed. Now Huygens found that either of the pencils separated by a first rhomb is affected by a second rhomb quite differently from a pencil of common light. When the second rhomb is placed with its faces parallel to the corresponding faces of the first rhomb, so that the two are in the same relative position as if they formed parts of a larger block of the crystal, each pencil separated by the first rhomb furnishes only a single pencil in the second rhomb, the ordinary only an ordinary, and the extraordinary only an extraordinary, the two being separated on emergence as much as if they had been transmitted through a single block having a thickness equal to the sum of the thicknesses of the two rhombs. If now the second rhomb be turned round the common normal to the adjacent faces of the two rhombs, each pencil transmitted by the first rhomb is immediately divided into two by the second rhomb, the pencil (O) which suffered ordinary refraction in the first rhomb furnishing besides the ordinary pencil (O O) in the second a faint extraordinary pencil (O E), and the pencil (E) which suffered extraordinary refraction in the first rhomb furnishing besides an extraordinary pencil (E E) in the second a faint ordinary (E O); the direction and amount of separation of the pencils O O and O E, and likewise of E O and E E, being those due to the azimuth and thickness of the second rhomb, while the direction and amount of separation of O O and E O, and likewise of O E and E E, are those due to the first rhomb. On continuing to turn, the faint pencils O E and E O become brighter and brighter, and the bright pencils O O and E E fainter and fainter, until the rotation amounts to 90°, when the original pencils O O and E E disappear altogether, the whole of the light of O (not counting the small portion lost by reflection) now passing into O E, and the whole of the light of E into E O. On further turning, the pencils O O, E E which vanished reappear, and appropriate to themselves more and more of the light of O, E, respectively, until the rotation amounts to 180°, when the pencils O E, E O vanish, while O O, E E become as bright as at first, their lateral separation being now, however, that due to the *difference* instead of the *sum* of the thicknesses of the rhombs. On continuing to turn, the same changes recur periodically, each pair of images vanishing alternately at every quarter of a revolution.

Now imagine the ordinary pencil O to be isolated by means of a screen, and presented for observation, the apparatus by which it was produced being hidden from the observer. By examining it with a rhomb of Iceland spar he could distinguish it at once from common light, which has no relation to any other direction in space than that of its propagation, whereas the pencil we have supposed possesses different properties with reference to different directions *transverse* to that of its propagation. By turning the rhomb with which he was furnished into either of the two opposite positions in which the extraordinary pencil vanishes, the plane of crystalline symmetry in the rhomb would mark a plane *determined solely by the properties of the pencil of light presented for observation*, and which (as well as its rectangular plane) is a plane of symmetry in relation to those properties. The plane of crystalline symmetry passing through the normal to the face of the rhomb is evidently parallel to a line bisecting either obtuse angle of the rhombic face, and contains the crystallographic axis. *Any* plane passing through this axis in Iceland spar is called in optical language a *principal plane*, because all such planes are planes of optical, though six of them only of crystallographic, symmetry.

If our observer were further informed that the light he had been observing was the ordinary ray transmitted through a rhomb of Iceland spar, he would be able to determine the azimuth of the principal plane of that rhomb, which would be the same as the principal plane of the rhomb with which he was furnished when the latter rhomb was turned till the extraordinary pencil disappeared.

Light possessing the properties which have just been described as belonging to the ordinary ray in a rhomb of Iceland spar, however these properties may have been acquired, is said to be *polarized*, and the plane to which the properties are related as are those of the ordinary ray to the principal plane of the crystal is called the *plane of polarization*. The polarization may be detected, and the azimuth of the plane of polarization determined, by means of a rhomb of Iceland spar, as above described.

The properties of a ray which emerges after extraordinary refraction in a rhomb of Iceland spar, as may be inferred from the description given above, are absolutely identical with those of the ordinary ray, except that they are similarly related to a plane perpendicular to the principal plane. Hence the extraordinary ray is polarized in a plane perpendicular to the principal plane, the ordinary ray being, according to our definition, polarized in the principal plane.

If a piece of Iceland spar, or other doubly refracting crystal, be cut into the form of a wedge or prism, the deviation of the two rays, into which a ray incident upon it is in general divided by double refraction, will not be the same, and thus the rays will emerge in directions inclined to each other, so that their lateral separation will increase with the distance from the prism. Two such rays are still found to be polarized, and their planes of polarization to be nearly perpendicular to each other, being accurately so when the refracting edge is perpendicular to a plane of optical symmetry, or *principal plane*, of the crystal, and the refraction takes place in that plane.

For more than a century after the original discovery of Huygens, double refraction was the only phenomenon in which light was known to receive the modification called polarization. But in the year 1808, Malus made the important discovery that light receives the same modification by reflection at a certain angle from the surface of glass, water, and transparent substances in general, provided their surfaces be smooth or polished, so as to give a regular reflection. The plane of reflection was found to be the plane of polarization of light thus polarized. The angle of incidence required for complete polarization by reflection was found to vary with the nature of the substance. At an angle of incidence greater or less than this (but not reaching 0° or 90°) the same modification was imperfectly produced, the light never vanishing on rotating the analysing rhomb, but only passing through a minimum in those positions in which at the polarizing angle it vanished altogether. The simplest conception to form of the nature of light thus partially polarized is to regard it as a mixture of common light and of light polarized in the plane of incidence. The refracted light is found to be only partially polarized even at the angle of complete polarization of the reflected light, the plane of polarization being perpendicular to the plane of incidence. It may be regarded as composed of a mixture of common light and of light polarized in the plane last mentioned; and it has been found that at the same angle of incidence the quantity of light polarized in the plane of incidence contained in the reflected beam is equal to the quantity of light polarized in the perpendicular plane contained in the refracted beam. When common light is reflected from a metal, the reflected light is only partially polarized in the plane of incidence, whatever be the angle of incidence.

Shortly after Malus's discovery of the polarization of light by reflection, Sir David Brewster commenced an extensive series of experiments on the polarizing angle of a variety of media, which resulted in the discovery of the beautiful law which determines the angle of polarization, namely, that the tangent of the polarizing angle is equal to the index of refraction, which may be otherwise expressed by saying that the angle requisite for complete polarization is that for which the directions of the reflected and refracted rays are perpendicular to each other. This law embraces, as a particular case, a law which Malus had already found, that when light is incident on a plate of glass or other medium bounded by parallel surfaces at the angle required for complete polarization of the light reflected at the first surface, the refracted light is also incident on the second surface at the angle of polarization for internal reflection. Accordingly a plate of glass, or a pile of plates, may be used instead of a single surface to furnish polarized light by reflection at the proper angle, and a pile of plates has the advantage of giving light of much greater intensity than would be got from a single surface.

Certain doubly refracting crystals have the property of absorbing very unequally the oppositely polarized pencils into which they divide an incident pencil of common light. Thus certain varieties of tourmaline, cut parallel to the axis of the crystal, when of a certain thickness, absorb almost completely the ordinary ray, and transmit a great portion of the extraordinary. Hence the light transmitted by such a plate is almost perfectly polarized, in a plane perpendicular to the axis of the crystal, and the plate may be used either for procuring polarized light in the first instance, or for examining light already polarized.

The general phenomenon of the relation of the properties of a polarised beam to directions transverse to the beam may be studied very simply in the case of polarization by reflection. It is sufficient to mount two pieces of glass, blackened at the back, so that the line joining their middle points is inclined approximately at the polarizing angle (about 54° 35′) to the surface of each, and that one of them is moveable about that line as an axis. The light of the clouds is reflected from the first glass on to the second, and from thence into the eye, which must follow the light in the rotation of the glass. When the planes of reflection coincide, the light is copiously reflected, but on turning the moveable glass on its axis the intensity diminishes, until on turning to 90°, when the planes of reflection become perpendicular to each other, a dark cloud is seen about the centre of the field, the middle of which is perfectly black when the adjustments are perfect, or at least would be so with homogeneous light. The experiment may even be performed by using the light polarized by reflection from a polished table, and examining it with a bit of glass, blackened at the back, which is held in the hand. In this way the splendid colours given, as will presently be mentioned, by thin plates of selenite, &c., may be seen perfectly well, by merely holding the plate in the path of the light incident upon the moveable mirror.

In any combination consisting of a piece (suppose a pile of plates), which may be called the polarizer, destined to furnish polarized light in the first instance, and of a piece (suppose a tourmaline or a Nicol's prism), destined to examine the light furnished by the polarizer, whether modified or not in its passage to the analyzer, if the analyzer be turned till the light is extinguished, and a rhomb of Iceland spar be introduced between the polarizer and analyzer, and be turned round, the light will in general be found to be more or less restored. In two rectangular positions of the rhomb, namely, when its principal plane is parallel or perpendicular to the plane of primitive polarization (that is, the plane of polarization of the polarized light incident on the rhomb), no effect is produced, and the field remains dark. But the moment the rhomb is turned from any one of these positions the light begins to reappear, and increases in intensity till the rhomb has turned 45° from the vanishing position, after which it again decreases by the same steps.

The nature of the restoration may be analyzed by placing a screen with a small hole on the face of the rhomb by which the light enters, so as to separate the emergent pencils. As these are polarized in planes depending, not on the plane of primitive polarization, but on certain directions fixed in the rhomb, and therefore no longer perpendicular to the plane of polarization of the analyzer, they are each partially transmitted by the analyzer. If the hole be now made larger, the partially transmitted images will overlap, and if the screen be taken away altogether the light perceived must still be regarded as a mixture of two beams, the ordinary and extraordinary respectively of the rhomb, each partially transmitted by the analyzer.

When a beam of polarized light is divided into two, polarized in rectangular planes, by a rhomb of Iceland spar, the intensity of either beam was assumed by Malus to vary as the square of the cosine of the inclination of its plane of polarization to the plane of primitive polarization, a law which was afterwards verified experimentally by Arago, and which applies equally to reflection from glass at the polarizing angle, the angle between the plane of reflection from the glass and the plane of polarization of the light incident upon it being now that of which the squared cosine varies as the intensity of the reflected light. If then, in our supposed experiment, the rhomb be turned till its principal plane is inclined at an angle i to the plane of primitive polarization, and if the intensity of the incident polarized light be taken as unity, the intensities of ordinary and extraordinary beams will be expressed by $\cos^2 i$, and $\cos^2 (i+90^\circ)$, or $\sin^2 i$, respectively. As the planes of polarization of these beams are inclined at angles $90^\circ - i$ and i respectively to the plane of polarization of the analyzer, the fractions of the beams transmitted by the analyzer will be measured by $\sin^2 i$, $\cos^2 i$, respectively, so that the whole intensity will be measured by $\cos^2 i \sin^2 i + \sin^2 i, \cos^2 i$, or $\frac{1}{2} \sin^2 2i$, which vanishes when $i=0$, or $=90^\circ$, &c., and has its maximum value $\frac{1}{2}$ when $i=45$, or $=135^\circ$, &c.

This restoration of light which has been described in the case of Iceland spar is manifested by doubly refracting crystals in general, and forms a very simple and delicate test of the existence of double refraction, which may be applied when, from the feebleness of the doubly refracting power or the thinness of the crystalline plate, it would be difficult or impossible to make out a separation of the images. It may easily be observed by using sulphate of lime or selenite, a common mineral, which has a very perfect cleavage in one direction.

But if the plate of selenite be very thin, not so thin however but that such a plate may be readily obtained by cleavage, a new and splendid class of phenomena make their appearance, as was discovered by Arago. In those positions in which a thick plate simply restores a portion of the light, a thin plate is seen arrayed in gorgeous colours, changing with every change of thickness, and varying too when the plate is considerably inclined. If the plate be fixed, and the analyzer be made to revolve, the colours change in a remarkable manner, and when the rotation amounts to 90° the original colour at any point is replaced by its complementary, so that the two superposed make white light. This law is found to hold good for *any* two azimuths of the analyzer separated by 90°, and not merely for the azimuths 0° and 90°.

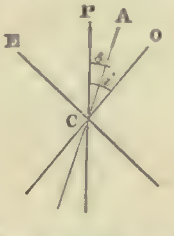
It would pass the limits of this article to describe the phenomena of the colours of crystalline plates in all their details, and the still more curious and complicated coloured rings or curves seen about the optic axis, or the two optic axes, of uniaxal or biaxal crystals. Indeed the subject has been introduced in this place only to enable the reader to form a better idea of the evidence in favour of the view taken in the undulatory theory of the nature of polarization.

The laws of the phenomena of crystalline plates were most carefully investigated by M. Biot and Sir David Brewster, and to account for them the former imagined his theory of *moveable polarization*. Dr. Young first showed that on the undulatory theory the retardation of one of the two oppositely polarized rays which passed through the crystalline plate relatively to the other was precisely that required to produce, by ordinary interference, the tint observed. Huygens's demonstration of the laws of reflection and refraction intimately connects refraction with velocity of propagation, and thereby permits of the retardation in question being calculated from the observed phenomena of double refraction, without making any assumption as to the nature of polarization. But it remained to be shown why no phenomena of interference should be perceived unless the light incident on the crystal were polarized, and the emergent light were subsequently analyzed.

It occurred to MM. Arago and Fresnel that it would be interesting to examine in what manner the interference of two rays of light, which, as regards length of path, are in a condition to interfere, might be modified by previous polarization of the rays. The memoir containing an account of this important investigation is published in the 10th volume (1819) of the 'Annales de Chimie,' p. 288, and a full account of it is given in Sir John Herschel's Treatise on Light. The laws of interference of polarized light in truth might have been obtained at once from the phenomena of the colours of crystalline plates *by assuming those colours to be due to interference;* but it was highly important at the time to establish them in a more direct manner, by the observation of what were incontestably fringes of interference. They may be thus briefly enunciated:—(1) Two rays of light coming from the same source, and polarized in rectangular planes, are incapable of interfering. (2) Two rays coming from the same source, and polarized in *the same* direction, interfere exactly like rays of common light. (3) Two rays coming from the same source of *common* light, and polarized in rectangular planes, may be afterwards analyzed without acquiring thereby the property of mutually influencing each other. (4) But two rays polarized in rectangular planes and afterwards analyzed, *do* interfere, provided they come from the same source of *polarized* light. (5) In the phenomena of interference produced by rays which have experienced double refraction, the character of the interference is not determined simply by the difference of path; it is necessary in certain cases to change this difference by a semi-undulation. The half undulation must be added or not according as the planes of primitive polarization and of analyzation lie in alternate pairs, or in the same pair of opposite quadrants made by the rectangular planes of polarization of the two polarized rays transmitted by the crystalline plate.

These laws, combined with Malus's law already mentioned, and with the formula which gives the intensity of the light resulting from the interference of two streams of light of known intensities and difference of path, enable us to calculate completely the colours of crystalline plates in polarized light without making any assumption as to what constitutes polarization.

Let C P be the plane of primitive polarization, C A that of analyzation, C O, C E the rectangular planes of polarization of the rays into which a ray of any kind is divided by the double refraction of the crystalline plate. Let i be the azimuth of C O, and s that of C A, both measured from C P. We may without loss of generality suppose i to be between the limits 0° and 90°, and s between the limits $i \mp 90°$. Further, let o, e, be the lengths of path in air equivalent in time of being described to the paths of the two rays respectively within the crystal; let λ be the wave-length in air belonging to any particular kind of light, and take the original intensity of that light as unity.



By Malus's law the intensities of the two streams, polarized along C O, C E, into which the original stream is divided by double refraction, will be $\cos^2 i \sin^2 i$, respectively. If each of these be again divided into two, polarized along and perpendicularly to C A, the intensities of the former portions will by the same law be $\cos^2 i \cos^2 (i-s)$, $\sin^2 i \sin^2 (i-s)$, respectively. The difference of phase of these portions will be $\frac{2\pi}{\lambda}(o-e)$. Now if I, I′ be the intensities of two streams of common light from the same source, ρ their difference of phase, the intensity of the light resulting from their interference will be $I + I' + 2\sqrt{(I I')} \cos \rho$. But by the second law of interference of polarized light this formula may be applied to the interference of two streams of polarized light which are capable of interfering, as by law 4 the two streams are which are polarized along C A. In the application of the formula we must take $\sqrt{I} = \cos i \cos (i-s)$, $\sqrt{I'} = \sin i \sin (i-s)$ or $= \sin i \sin (s-i)$, according as $i > s$ or $i < s$. But by law 5 when $i < s$ we must change the actual difference of path by half an undulation, that is, change ρ by π, or, which comes to the same, change the sign of one of the radicals $\sqrt{I}$ or $\sqrt{I'}$. Hence it will suffice to take $\sqrt{I'} = \sin i \sin (i-s)$ in all cases, and omit the addition or subtraction of the half undulation. Hence the expression for the intensity will become

$$\cos^2 i \cos^2 (i-s) + \sin^2 i \sin^2 (i-s)$$

$$+ 2 \cos i \sin i \cos (i-s) \sin (i-s) \cos \frac{2\pi}{\lambda}(o-e) \quad . \quad . \quad . \quad . \quad . \quad . \quad (A)$$

which may be readily transformed into the more simple expression

$$\cos^2 s - \sin 2i \sin 2(i-s) \sin^2 \frac{\pi}{\lambda}(o-e) \quad . \quad . \quad (B)$$

The discussion of either of these expressions would give account of the observed phenomena of the coloration of crystalline plates in polarized light, but would exceed our limits. Suffice it to remark that in the expression (B) the first term denotes the illumination, alike for all colours, which would exist if the plate were removed, while the second changes materially from colour to colour, in consequence of the variation of λ, in comparison of which the variation of $o-e$ may usually be neglected.

Now the study of the phenomena of light which are independent of polarization leads us, and that in different ways, to the conclusion that with light of given wave length the square of the amplitude of vibration must be taken as the measure of intensity, and consequently the amplitude of vibration will vary as the square root of the intensity. If now, bearing this in mind, we go over the whole investigation of the colours of crystalline plates, beginning with the first application of Malus's law, and deducing at every step from the intensities which are the objects of direct observation the corresponding amplitudes of vibration, we can hardly fail to be impressed with the idea that in polarized light the vibrations of the ether take place in a rectilinear manner in a direction *transverse* to that of propagation, and related in some constant manner to the plane of polarization. Unquestionably there must be a transverse *something* about polarized light which admits of composition and resolution in that way. Now polarized light in all its relations is symmetrical with respect to the plane of polarization and the perpendicular plane, and to no other. For example, when light is polarized by reflection at the surface of glass, everything must evidently be symmetrical with respect to the plane of reflection. Hence our rectilinear vibrations must also be symmetrical with respect to the plane of polarization, and therefore must either be in or perpendicular to that plane.

But if such be the nature of polarized light, what notion must we form of the nature of common light? We have seen that common light, in passing through a rhomb of Iceland spar not limited by a screen, is resolved into two polarized streams, which, mixing on emergence, yield a light having all the properties of common light. Nor does the light reflected from the first surface of the rhomb possess any other properties: it may be polarized like common light, or divided by another rhomb into two polarized streams which mix on emergence just as before, so that there is not the slightest ground for supposing that with the light lost by reflection the original beam loses any element of a different character from that which it retains. It is easy to make out the nature of the vibration which results from the coexistence of two series of rectilinear and transverse vibrations propagated in the same direction and taking place in rectangular planes. The vibrations in such a case would take place in planes perpendicular to the direction of propagation, that is, would lie in the fronts of the waves.

Hence the following important suppositions are adopted in the theory of undulations.

The vibrations of the ether which constitute light, unlike those of air which constitute sound, take place, not to and fro in the direction of propagation, but laterally in the tangent planes of the waves. In polarized light the vibrations are rectilinear, and either parallel or perpendicular to the plane of polarization, a point which for the present may be left undecided. *The polarization of common light consists in the resolution of the vibrations into two rectilinear series, the undulations belonging to one of which are obtained apart from those belonging to the other.*

The theory of transversal vibrations was first suggested by Dr. Young, who was led to it by the consideration of certain phenomena of biaxal crystals discovered by Sir David Brewster. It suggested itself independently to the mind of Fresnel, who was led to it by considering the laws of interference of polarized light, made out by Arago and himself. It encountered, at first, much opposition, for it was entirely opposed to preconceived notions. It obliges us in fact to suppose that the vibrations which constitute light are carried on, not by forces by which the ether tends to resist condensation or rarefaction, but by forces by which it tends to resist *distortion*, unaccompanied by change of volume. We are driven to conceive that a sliding motion of the ether, layer over layer, is resisted by a tangential force thereby called into play: in fact, to treat the ether, so far as the vibrations of light are concerned, as if it were an elastic solid. Still, it would ill accord with the spirit of inductive philosophy to reject a conclusion to which we are fairly led by the study of observed phenomena, because it clashes with preconceived notions respecting the nature of a medium of the very existence of which we have no evidence beyond the beautiful and simple explanation it affords of the curious and complicated phenomena of light.

If once we adopt the theory of transversal vibrations, we are able not only to form a clear picture in the mind of what, to say the least, polarization may be, but to explain in the simplest manner both Malus's law and the laws of interference of polarized light. In fact, Malus's law and laws 2, 4, 5, of interference led to the theory of transversal vibrations; and to explain these laws on the theory we have only to begin at the other end. Laws 1 and 3, which assert the necessity of a polarizer in order that any colours should be seen in crystalline plates, follow at once from the consideration that the rectangular components of the vibrations in common light have no fixed and permanent relation to each other, either as to phase or amplitude, so that they are *as good as* the vibrations belonging to two streams from different sources.

The theory of transversal vibrations, again, enables us to form a perfectly clear notion of the nature of a peculiar modification of light, known as elliptic polarization. When polarized light is transmitted across a crystalline plate, the emergent light is in general elliptically polarized, being only in particular cases polarized in the way hitherto considered in this article, or *plane-polarized*, as it is called in contradistinction to elliptic polarization. When elliptically polarized light is examined by an analyzer which is made to revolve, the light never wholly vanishes, but becomes alternately a maximum and a minimum at every quarter revolution. Thus far it agrees with partially polarized light, from which, however, it wholly differs in other respects, both theoretically and experimentally. [ELLIPTIC POLARIZATION.]

Lastly, the theory of transversal vibrations is, to say the least, very hopeful in its application to the explanation of double refraction, of the polarization of light by reflection, &c. The full explanation of these phenomena is retarded by two causes, first, there are the inherent mathematical difficulties of the problem, and secondly, which is far worse, in our ignorance of the ultimate constitution of matter, and its relation to the luminiferous ether, we have to grope in the dark in our endeavour to find out what is the real state of things to which our mathematics have to be applied. Still, even in this department many important laws have already been explained, and frequently even predicted, on dynamical principles, though not always with perfect rigour; but no dynamical theory has yet accumulated in its favour such a weight of evidence as to exclude others, nor can even the question whether the vibrations of polarized light are parallel or perpendicular to the plane of polarization be yet considered settled, though the probability seems to be in favour of the latter view, which was that originally adopted by Fresnel.

In this article the subject of double refraction has not been touched except so far as was necessary for the explanation of polarization. For further information on this point see a subsequent article, UNDULATORY THEORY.

POLARIZATION, MOVEABLE. This term refers to an ingenious theory by which M. Biot attempted to explain the colours of crystalline plates in polarized light. The theory is, however, liable to some formidable objections; and as the phenomena have since been explained in the most simple and complete manner on the theory of undulations [POLARIZATION] the reader who wishes for further information on this subject is referred to M. Biot's original paper in the 13th volume of the 'Mémoires de l'Institut.'

POLARIZED RINGS. The beautiful coloured rings or curves seen with polarized light about the optic axis or axes of doubly refracting crystals. [UNDULATORY THEORY.]

Q

Q is a superfluous letter of the alphabet, having the same sound as *k*, though limited to words where a *u* follows. This letter furnishes evidence that the alphabetical characters were originally of syllabic power. Thus the Hebrew koph and the Greek koppa appear to have been used only in those words where the sound of *o* follows, as in Cos, Corinth, and Syracosii, &c. Indeed the name of the letter implies as much. The Greek alphabet probably stopped at one period like the Hebrew, at τ, so as to have no *u*. On the other hand, the Etruscan alphabet had a *u*, but no *o*. Hence in Italy, the *q*, which, by position in the alphabet, corresponds to the Greek koppa, was limited to words where a *u* followed. In the same way the kaph of the Hebrew and kappa of the Greek were probably at first limited to those words where an *a* follows, as we know was the case in Latin; and as the modern name of the letter, *ka*, denotes, for it would otherwise have been called *ke* or *ek*. This view becomes more complete if it be called to mind that the name of χ connects it with the vowel *i*; and that the η or H of the Greek alphabet was originally a guttural aspirate, sounded perhaps as χη, and thus was adopted to denote either a guttural consonant or a long *e*. For the various forms of the symbol *q* see ALPHABET, and for the changes to which the letter is liable see C and K.

QUADI, an ancient people of Germany, who inhabited the country north of the Danube, between that river, the mountains of Bohemia, and the river March. Towards the north they bordered on the Marcomanni, in connection with whom they are frequently mentioned by the Roman writers as allies. Tacitus ('German.,' 42) mentions the Quadi, the Marcomanni, and the Narisci as being in the foremost rank among the German nations towards the borders of the Roman empire, the Danube forming the line of demarcation between the power of Rome and German independence. At a later period the Quadi joined a great confederacy of German nations against Rome, which occasioned much alarm to the empire, and which twice obliged the emperor Marcus Aurelius Antoninus to repair to Germany at the head of his legions. They are afterwards mentioned by Eutropius as having invaded Pannonia in the reign of Gallienus.

QUADRANGLE and QUADRILATERAL (four-angled and four sided). These terms are indiscriminately used to denote a figure with four sides in the same plane. [PARALLELOGRAM; RECTANGLE; SQUARE; TRAPEZIUM; RHOMBUS.]

QUADRANT. [SEXTANT.]

QUADRANT. As an astronomical instrument, the quadrant has within a few years been so completely superseded by the entire circle, that it will not be worth while to describe particularly its construction or adjustments. Still so much of the very groundwork of modern astronomy depends on data furnished by the quadrant, that it cannot be properly passed over without some notice.

We have already said [CIRCLE] that the earliest form of instrument for measuring celestial altitudes was also the best, namely, the solstitial or meridian circle described by Ptolemy. After showing how the proportion which the arc between the tropics bears to the whole circumference was to be determined by this instrument, Ptolemy proceeds to say ('Amalgest,' book i., chap. 10), "We have made this sort of observation more conveniently by using, instead of circles, a stout quadrangular block of wood or stone, having one side plane and smooth. Upon this side we described a fourth part of a circle from a centre near one of the angles, and having drawn from the centre two radii including a right angle, we divided the circumference into ninety degrees with subdivisions. We then inserted two perfectly equal cylinders at the extremities of the vertical radius, so as to be exactly concentric with the centre and extreme point, and set the block vertical by a plumb-line passing over the cylinders, and also in the plane of the meridian by a north and south line described on the horizontal plane. We observed at noon the shadow of the central cylinder, having applied something to the divided arc to show the place more clearly, and, marking the middle point, we took the corresponding division of the quadrant as showing the elevation of the sun on the meridian." It would seem that on the revival of learning, when Ptolemy was thought infallible, the quadrant came into use on this authority, to the exclusion of the circle. In the 'Astronomiæ Instauratæ Mechanica' of Tycho Brahé, figures and descriptions will be found of quadrants and sextants of various forms and sizes. We do not think justice is done at the present day to the merits of Tycho, who is better known as the perplexer of the Copernican hypothesis, than as the first great practical astronomer after Hipparchus. Among his numerous instruments Tycho had a large quadrant fixed on a wall, which he calls a *mural* quadrant, with which he observed meridian altitudes, noting the time of transit by a clock. There are several other quadrants figured and described, which revolve on a vertical axis, and some have a horizontal circle by which the azimuth was observed at the same time with the altitude. These may be considered as the precursors of the modern astronomical quadrant, and still more perfect altitude and azimuth instrument, just as his mural quadrant led to the mural arc of Flamsteed, the mural quadrants of Bird and Ramsden, and finally to the mural circle of Troughton. The imperfection of his clocks (for the pendulum was not applied till nearly a century later) compelled Tycho to adopt an instrument which has long been out of use. This was his astronomical *sextant*, which was stronger, more convenient, and lighter than the quadrant. It was supported at the centre of gravity on a ball and hemispherical cup, and could consequently be easily placed in the plane passing through two stars, and so used for measuring their distance from each other. To verify the value of the arc, and to test the powers of his sextants and quadrants, the distances of a chain of stars near the equator were taken, and their declinations also observed, when it was found that the sum of the angles at the pole which resulted from observation was 360° very nearly. (Tycho Brahé, 'Astronomiæ Instauratæ Progymnasmata,' pp. 138, 145.)

Hevelius has described his quadrants and sextants in the first volume of his 'Machina Cœlestis,' a work which is not uncommon; the second volume, containing his observations, was burnt soon after it was printed, with the exception of a few copies, and is one of the scarcest and dearest astronomical books in existence. In the convenience of his instruments, and perhaps in the accuracy of their graduation, he surpassed Tycho, but he never could understand the advantage of telescopic over plain sights, though one of the best practical opticians and industrious star-gazers of his time. This unfortunate prejudice not only rendered the labour of his long life labour in vain, but embittered his latter years to a painful degree by involving him in a dispute with Hooke.

Picart, aided, as it is said, by Auzout, first applied telescopic sights to graduated instruments. In his measure of the earth, executed in 1669 and 1670, he used a quadrant for his terrestrial angles. This he has described, with figures, in a special work, printed at the Louvre, which became so rare that the 'Académie Royale des Sciences' reprinted it in their Memoirs (vol. vii., part i., p. 133). The quadrant was of 38 inches radius, with one telescope fixed in the direction of one radius, and the other moveable about the centre; the arc of the instrument was divided by transversals, and the angle read off by the index of the moveable telescope was equal to the angle subtended at the quadrant by the objects bisected by the cross-wires of the two telescopes. The instrument could be fixed on its stand with the plane vertical when used for altitudes, and by an additional piece, a *genou*, was moveable into any other plane, when it was wanted for surveying. The whole turned on a vertical axis, like Tycho's azimuthal quadrants, but without an azimuthal circle. Quadrants like Picart's continued to be made by the French artists and used by their astronomers (with some improvements, of course) up to the latter end of the last century, when they were superseded by the repeating circle of Borda. The verification of the arc and of the graduation was performed in Tycho's manner, only employing well defined objects in the horizon instead of stars.

For a fixed observatory Picart and Roëmer recommended a large quadrant permanently fixed, that is, a copy of Tycho's mural quadrant, with the changes which telescopic sights required. Lemonnier, in the preface to his 'Histoire Céleste,' says that La Hire had one erected in the Royal Observatory at Paris, in 1683, and that it was described in the first edition of La Hire's tables. This description he repeats at page xlii. of his work.

Flamsteed made his earlier observations at Greenwich with a sector, the plan of which may be understood by conceiving one of Tycho's sextants with telescopes, instead of plain sights, to be mounted on a polar axis. ('Historia Cœlestis,' vol. iii., p. 103.) This instrument was designed for measuring the distances of stars from each other. But in pursuing his primary object, that of settling the places of the fixed stars with accuracy, Flamsteed found that he required a *meridian* instrument. Some unlucky trials at constructing a quadrant were made by the person employed by the Royal Society, and Flamsteed finally constructed, at his own expense, and by Abraham Sharp's hands, the mural arc with which he observed from 1689 to his death.* (See the description and figure, 'Historia Cœlestis,' vol. iii., p. 108.) This differed from other mural arcs chiefly in this, that it contained 140° or 150°, so that all stars were observable with it, from Polaris, below the pole, to the south horizon. The arc was placed as nearly in the meridian as might be, and the errors in its plane detected by comparing the observed time of the sun's passage over the middle wire of the instrument, with the true time of his meridian passage, as deduced from corresponding altitudes with a quadrant. The pendulum clock, though as yet not a very perfect instrument, had by this time entirely done away with the necessity of observing the mutual distances of the stars.

---

* Among the *real* injuries which Flamsteed received, we consider the translation of his preface into indifferent Latin one of the greatest, though committed with a friendly intention.

When Halley succeeded Flamsteed at Greenwich, the observatory appears to have been dismantled. Halley saw the great superiority of Roemer's *transit* over every other instrument for ascertaining right ascension, and accordingly introduced it; but he seems not to have perceived the advantages which Roëmer's *circulus meridionalis* possessed over any segment of a circle. In 1725 a mural quadrant was erected by Graham, which was superior to any previous instrument of this construction; it had however one grievous imperfection: the radii being of iron and the arc of brass, every variation of temperature altered the value of the total arc. In 1750, this quadrant, which was subsequently known by the name of the iron or north quadrant, was removed to the other side of the pier, and the celebrated quadrant by Bird set up in its place. Of Bird's method of dividing we have given some account in the article GRADUATION. His reputation, which was a good deal based on this quadrant, introduced similar instruments by himself or Ramsden into almost every observatory of note. Bird received 500*l.* from the commissioners of longitude for his 'Method of dividing Astronomical Instruments,' and the work was published by their order in 1767. We are not aware that a more perfect quadrant than the Greenwich *brass* or *south* quadrant was ever constructed. It was with this instrument Bradley made his invaluable observations, which have been reduced with consummate skill by Bessel. ('Fundamenta Astronomiæ deducta ex Observationibus viri incomparabilis James Bradley, autore F. W. Bessel, Regiomonti,' 1818.) There is in this work a careful examination of the errors to which the two quadrants were liable.

When the portable quadrant was wanted for astronomical purposes, the plane was fixed vertically, and it is then usually called an astronomical quadrant. A great many instruments of this construction were made by Bird, Ramsden, and the Troughtons, in the latter half of the last century, and in careful hands a great deal of work may be done with such a quadrant.* Thus observations of the sun or stars at the same altitude on each side of the meridian will furnish an excellent determination of the time, and zenith distances of stars near the zenith in reversed positions of the instrument (the excess arc, as it is called, affords the means) will yield a good latitude. Observations of northern stars combined with southern stars at similar altitudes will give a very close approximation to the latitude when the true places of the stars are taken from a good catalogue. For the mode of adjusting and using the quadrant we must refer to the older books or encyclopædias which treat of astronomical instruments. The inferiority of the quadrant to the entire circle is such that there is no probability of its ever returning into fashion, and we believe there is not a single public observatory in which it is now in use. The single advantage of the quadrant is that the divisions are larger and consequently more easily read and subdivided than in a circle with the same telescope. But this trifling superiority is much more than compensated by the power of reading off the circle at several points and taking the mean. On the other hand it is impossible in the quadrant to secure the exactness of the total arc, or the concentricity of the centre of motion and the centre of the divisions, while the necessity of leaving some liberty of motion to the axis carrying the telescope allows of a little wandering of the centre-work, which is perpetually shifting its place. Thus it was found that in the celebrated Greenwich quadrant, though the error of division was probably not more than 1″, the uncertainty arising from other causes might easily be 3″ or even more. Again, in the mural quadrant it seems difficult so to support it as to resist the long continued effort of gravity in altering its form, without at the same time rendering it unstable. The Greenwich quadrant was found to have sensibly altered its shape, that is, it had become flattened about 45°, and pulled out at the two extreme radii, which was shown by the errors in the places of stars observed by it when compared with their places by circular instruments, and also by an actual measurement of the several radii and chords. For more minute information the reader is referred to Lalande's *Astronomie*, § 2311, &c., 3me. edition; Vince's *Practical Astronomy*, chapter v.

QUADRANT. Halley's quadrant is the name sometimes applied to the octant of reflexion which measures an angle of 90°. The principle is that of the SEXTANT.

QUADRANTAL, a name formerly given to a spherical triangle one side of which is a quadrant.

QUADRATIC, BIQUADRATIC (*quadratum*, a square), names given to algebraic expressions, the highest powers of which are the square, and the square of the square, or fourth power, of the letter with reference to which the expressions are considered. [THEORY OF EQUATIONS.]

QUADRA'TRIX, a name given to curves which may be made useful in the QUADRATURE of other curves. There is one known by the name of Dinostratus, the equation of which is—

$$y=(a-x)\tan.\left(\frac{x}{a}\,90^\circ\right),$$

which curve being given, the ordinate, when $x=a$, determines the length of the circle whose radius is a, as follows:- Make a rectangle on this ordinate equal to the square of the diameter, and the other side of that rectangle is the circumference of the circle.

The quadratrix of Tschirnhausen has for its equation—

$$y=a\sin\left(\frac{x}{a}\,90^\circ\right),$$

and this curve being given, and also the method of drawing a tangent to it, the circumference of a circle may be thus found: Draw a tangent at the origin, and draw a right-angled triangle with a part of this tangent for the hypothenuse, and a part of the axis for a base: the other side is then the quadrant of a circle which has the base for a radius.

Various other modes might be found of making either of these curves square the circle; but the fact is, that the description of the curves themselves assumes the point which their use is to determine.

QUADRATURE. By the quadrature of a curve is meant the finding of a square equal to the content inclosed by the curve; but as every rectilinear figure can be immediately converted into a square of equal magnitude, the object is gained so soon as *any* rectilinear figure is found of the same content as the curve. This is the geometrical quadrature of a curve. The arithmetical quadrature is the determination of the area inclosed by the curve in terms of a given square unit, as a square foot; and if this be done with any required amount of accuracy, the quadrature, thus done sufficiently for practical purposes, is spoken of as an absolute quadrature. The two following articles will in various places illustrate the preceding description of the meaning of the simple word.

QUADRATURE OF THE CIRCLE. The speculative part of this question might be passed over with a slight description of the means of finding a square equal to a given circle, or of expressing a circle by means of the square on its radius, if it were not that it is connected with one of those propensities, the love of the marvellous, which, carried to an undue extent, tend more than others to throw the mind off its balance, and destroy the comfort of the individual. When it is considered that there are still persons who spend their time, means, and energies in the attempt to overcome a difficulty of which they do not even know the character, it is worth while to enter a little more at length upon this celebrated question of the quadrature of the circle than its mathematical importance would seem to require. We may add that its historical importance is very great.

It is a proposition not very difficult of proof, that if a right-angled triangle have the radius of a circle for its base, and a line equal to the circumference for its altitude, the triangle is equiareal with the circle. Hence the quadrature is reduced to the finding a line equal in length to the circumference, either geometrically or arithmetically; or to finding an answer to one or other of the following questions:—

Given a, the diameter of a circle in units of a given kind, required a number or fraction π, such that a multiplied by π may be the number of those same units in the circumference. It is easily shown that this number π must be the same for all circles.

Given the diameter of a circle, required *geometrically* a method of drawing a straight line equal in length to the circumference.

Those who first proposed these questions found their progress arrested by the insufficiency of their arithmetic and the limitations of their geometry. The former question has long been settled, and it has been shown that the ratio of the circumference to the diameter is INCOMMENSURABLE. The latter question cannot be called finally settled, since there is no proof in which all agree that the *geometrical* quadrature is impossible, though there are considerations which render it in the highest degree unlikely, and there are also asserted proofs of the impossibility which some admit, and which make even those who do not absolutely admit them think their conclusion all but proved. But the mistake of those who produce pretended quadratures often lies in this, that they do not know what is meant by the word *geometrical*. They imagine that anything is geometrical which deals in notions about space, and deduces that which is not obvious from that which is. But geometry, in the technical sense, is that which results from the use of Euclid's postulates [AXIOM], which permit nothing but the junction of two points by a straight line, the indefinite production of that joining line, and the description of a circle with a given centre, and the line joining that centre with another given point as a radius. These limitations make the whole difficulty; otherwise nothing would be more easy than to determine a circle by the QUADRATRIX, if that were allowed to be drawn, or to suppose a circle to roll on a straight line till the point which first touched the straight line touches it again, in which case the line rolled over is the length of the circumference. When, therefore, any one imagines, as is often the case, that he has found a method of squaring the circle, it generally happens that he only announces the not very new nor surprising fact, that a difficulty which exists under certain circumstances may be no difficulty at all under others. But in like manner as no one would be held likely to answer the question "Required the way of building a house without the use of iron," who should first demand a common hammer and nails, so the greater number of persons who attempt to square the circle must not be supposed to meet the geometrical difficulty by assuming powers of which geometry expressly requires the use to be abandoned, until it can be shown to be given in allowing the simple postulates above mentioned.

---

* A very perfect specimen of the astronomical quadrant is described in Pearson's 'Astronomical Instruments,' vol. ii., p. 554.

Aristophanes introduces into his comedy of the Birds a geometer who is going to make a square circle. Plutarch asserts that Anaxagoras employed himself upon this problem in prison. Hippocrates of Chios actually found the way to make a rectilinear space equal to certain circular spaces, and is reported to have attempted the general problem. There is evidence enough that it acquired an early celebrity, and it may be doubted whether the researches of Euclid in incommensurables [IRRATIONAL QUANTITIES] had not some reference to a supposition that the circle and its diameter might possibly be discovered to belong to a particular class of these quantities. Archimedes, in his book on the mensuration of the circle, is the first who made any approach even to a practical determination of the question. By inscribing and circumscribing polygons of 96 sides in and about the circle, he demonstrates that the excess of the circumference over three times the diameter must be less than 10-70ths of the diameter, and greater than 10-71st parts. His limits are perfectly correct, and even tolerably close. According to him, a circle of 4970 feet diameter would have a circumference lying between 15,610 and 15,620 feet, the truth being that such a circle would have a circumference of 15,613¾ feet very nearly. This measure of Archimedes gives 3·14286 for the approximate value of π, the ratio of the circumference to the diameter; several of the Greeks are said to have made further approximation, but their results are not preserved.

Among the Hindus [VIGA GANITA, in BIOG. DIV.] are found the ratios of 3927 to 1250, and also that of the square root of 10 to 1. The first gives $\pi = 3·1416$ exactly, and is considerably more correct than that of Archimedes; the second gives 3·1623, and is much less exact. The date of the first result is not known; but all agree that the writings in which it is found are anterior to any European improvement on the measure of Archimedes. The ratio given by Ptolemy, in the Syntaxis, is 3·141552, not quite so correct as 3·1416, but so near to it that those who doubt of the antiquity of Hindu science will probably suppose the 3·1416 above mentioned to be a version of Ptolemy's measure.

This subject began to be reconsidered in the 16th century, in the middle of which were calculated the tables [TABLES] of Rheticus, the celebrated Copernican, from which the value of π might easily have been calculated to eight decimals, but it does not appear that this was done. Purbach used the ratio of 377 to 120, or 3·141667, not so exact as Ptolemy's. Regiomontanus slightly corrected the limits of Archimedes, but Peter Metius, father of Adrian (to whom it is often attributed, merely because Adrian records and delivers it), and of James (to whom the invention of the telescope has been given), made a decided improvement. He gives the ratio of 355 to 113, or 3·14159292, which is correct to the sixth decimal inclusive. Nothing more precise could be desired for practical purposes, insomuch that a circle of 113 in diameter may be reckoned as one of 355 in circumference, which, though a little too great, does not give the circumference wrongly by so much as one foot in 1900 miles. On looking, however, at the account which Adrian Metius gives of his father's investigation, we find that the extreme closeness of the approximation is only a piece of good fortune. As it is very curious that this should never have been noticed, we quote the whole passage:—"Parens meus Illustrium D.D. Ordinum Confœdaratarum Belgiæ Provinciarum Geometra, in libello quem conscripsit adversum quadraturam circuli Simonis à Quercu demonstravit proportionem peripheriæ ad suam diametrum esse minorem quam $3\frac{17}{120}$, hoc est $\frac{377}{120}$, majorem vero quam $3\frac{15}{106}$, hoc est $\frac{333}{106}$, quarum proportionum intermedia existit $3\frac{16}{113}$, sive $\frac{355}{113}$. Quæ quidem intermedia proportio aliquantulum existit major, quam ea, quam invenit Mr. Ludolph à Collen, cujus tamen differentia est minus quam $\frac{1}{1000000}$." The book of Peter Metius was never published, that we can find; and we doubt if Adrian Metius would have published his father's result, if it had not come so very near to the then recent result of Van Ceulen. It seems that the elder Metius, finding $\frac{17}{120}$ too great, and $\frac{15}{106}$ too small, took the mean of the numerators for a numerator, and the mean of the denominators for a denominator, and presumed that the result was nearer the truth than either limit: a presumption to which he had no right whatever, except that of trusting to the chapter of accidents.

Metius lived in the latter half of the 16th century, as also did Vieta, who gave a still more accurate though not so elegant a measure. He was the first who exhibited a series of arithmetical operations by which a mere calculator might carry on the process to any extent, and gave the following result: The circle whose diameter is ten thousand million of parts, has a circumference greater than 31,415,926,535 of those parts, and less than 31,415,926,537. Other approximations rapidly followed: Adrianus Romanus calculated the perimeter of an inscribed polygon of 1073741824 sides, by means of which he found for the ratio 3·141592653589793; but his contemporary Ludolph van Ceulen, by calculating the chords of successive arcs, each of which is the half of the preceding, found the perimeter of a polygon of 36893488147419103232 sides, and obtained 36 figures of the ratio 3·14159, &c., presently given to a still greater length. So far the method of calculating by means of inscribed polygons, though Vieta had reduced it to routine, had received no material simplification. This was given by Snell, who found some propositions (afterwards demonstrated by Huyghens) which very much abridge the labour. He found a result as correct as that of Archimedes, by means of a simple hexagon; making the 96-sided polygon of Archimedes give seven decimals correctly, instead of three. He also calculated the ratio to 55 decimal places, and by means of a polygon of only 5242880 sides. Huyghens introduced some new theorems of the same species as those of Snell.

The invention and cultivation of the differential calculus led to many new views and new methods, into which it is not our purpose to enter, as we intend the present article not for mathematicians, but for those who have just enough of the science to think it possible that the solution of the problem is reserved for them. The continued product of Wallis, the continued fraction of Brounker, the series of Mercator, Gregory, Newton, &c., were so many new algebraical expressions of a result which, one might imagine, would be considered as carried far enough by the arithmetician. Nevertheless the ratio was consecutively carried to 75 places by Abraham Sharp, to 100 by Machin, and to 128 places by De Lagny, and at the end of the last century to 140 places by Vega. And Baron Zach gave Montucla the copy of a manuscript * in the Radcliffe Library at Oxford, in which it was carried to 154 places.

Vega's result, which, so far as they go, is confirmed by those of Machin and De Lagny, is wrong only in the last four figures. The Oxford manuscript is wrong only in the last two.

In the year (1841) in which this article was first published, Dr. Rutherford communicated to the Royal Society 208 places of decimals. Of these, however, it was afterwards found that the last 56 were incorrect; and so, it was found, were the last two figures of the Oxford result: that is, the Oxford manuscript and Dr. Rutherford were correct just as far as they agreed. About 1846, Mr. Dase [TABLES], a very powerful mental calculator, calculated 200 decimals; and in 1847, Dr. Clausen, of Dorpat, calculated 250 decimals, by two methods. ('Astr. Nachr.,' No. 489, according to Mr. Shanks.) In 1851, without being aware of what Dr. Clausen had done, Mr. William Shanks [TABLES], of Houghton-le-Spring, Durham, calculated 315 decimals, which Dr. Rutherford verified, and extended to 350 decimals. In 1851-52, Mr. Shanks extended his calculation to 527 decimals, while Dr. Rutherford independently calculated 441. In March and April, 1853, while Mr. Shanks was passing a very full account of his 527 figures through the press, he extended it to 607 decimals, and gave the result in 'Contributions to Mathematics,' London, 1853, 8vo. Accordingly, this famous result is now certainly obtained to 441 decimals, and with high probability to 607.

We give Mr. Shanks's result, and also his values of the base of Napier's logarithms, and of the modulus of Briggs's system; three numbers which are often wanted together. The figures between the rules, and those in the lowest row, are to enable the reader to detect and correct any error of printing, or to decide upon any defaced figure. The number between the rules is the sum of the ten preceding digits; and the number in the lowest column is the unit's figure of the sum of the whole column. Thus 1415926535 has digits which sum into 41; and 1584447730952 has digits which sum into 59, of which the 9 is written below.

[*] On making inquiry at the Radcliffe Library, we find that no such thing is known to be there, nor has been known for the last forty years at least. The inquiry has often been made, and every search has been unproductive. Baron Zach must certainly have seen such a manuscript somewhere: for, though fond of a hoax among friends, it is incredible that he should have *correctly* calculated the result sixteen places further than had been done, merely to make Montucla believe in an Oxford manuscript. Montucla does not say that Zach saw a manuscript upon the subject: but only that he saw the result *in a manuscript*. It may be that the figures were only jotted down on a fly-leaf, or something of that sort: if not, Zach must have failed to remember *where* he saw the figures; a thing in itself very unlikely.

These excesses of calculation are useful in showing the way, and in destroying that belief in the impracticability of extending what has been done which has retarded the progress of many subjects. The 607 decimal places give no sufficient notion of their amount of accuracy; or rather, give no sufficient notion of the impossibility of placing the amount of accuracy before the imagination. But the following illustration has a tendency to do what is wanted.

The blood-globules of some animalcules are a millionth of an inch in diameter. Let there be an inhabited globe so large that our great globe is but fit to be a blood-globule in the body of one of its animalcules; and call this the first globe *above us*. Let the *second* globe above us be so large that the *first* globe is but as one of the blood-globules in it; and so on to the *twentieth* globe above us. Next, let one of the blood-globules on our globe be an inhabited globe, with everything in proportion; and let this be the first globe *below us*. Let the *second* globe below us be but a blood-globule in an animalcule of the *first;* and so on to the twentieth globe below us. Then if the inhabitants of the twentieth globe above us were to calculate the circumference of their globe from its diameter by help of the 607 decimals, the inhabitants of the twentieth globe below us could not detect the error with their best microscopes, unless their Tulleys and Rosses were much greater masters of their art than ours.

The newest attempt at quadrature of our century is that of Mr. R. Ambrose Smith, of Aberdeen. It was undertaken as a test of the theory of probabilities. If a thin rod, not so long as the breadth of a plank, be thrown at hazard upon a planked floor, the chance which the rod has of intersecting a seam between two planks is the fraction which the length of the rod is of the quadrant having the breadth of a plank for its radius. In 3204 tosses with a rod three-fifths of the breadth of plank, the experimenter found 11 mere contacts, and 1213 decided intersections. He counted the contacts as intersections, and, from the principle [PROBABILITY] that the result of a large number of trials is nearly that of the long run, he presumed that 3 is to the quadrant of radius 5 nearly as 1224 to 3204. This gives 3·1412 for the ratio of the circumference to the diameter; which comes nearer than Archimedes. If, which perhaps ought to have been done, the contacts had been equally divided between intersections and non-intersections, the result would have been 3·1553: and even this is a remarkable approach, the nature of the method being considered.

The never-ending character of these numerals, so far as they were tried, led to an early suspicion that the ratio must be really incommensurable. This was actually proved by Lambert ('Mém. Acad. Berlin' for 1761), and the demonstration has been given in an abridged form by Legendre, in the notes to his work on geometry. This demonstration is perfectly complete, and leaves no manner of doubt on the subject. Those who persist in asserting that they can assign two numbers which are in the ratio of the circumference to the diameter, should first learn geometry and algebra enough to refute this proof, for they may depend upon it that no mathematician will lend them a moment's attention until this preliminary step has been taken. Buffon, and Panckouke, the editor of the 'Encyclopédie Méthodique,' have attempted to give metaphysical reasons for this incommensurability, apparently in order that the squarers of the circle might not have all the nonsense on their side of the question.

Proof of the impossibility of the *geometrical* quadrature, as above described, was attempted by James Gregory, in 1668; and Montucla seems to admit the proof at last,* though he only said that it was *very like demonstration* in the first edition of his work on the history of this problem. The objections made by Huyghens to this proof, and the controversy which ensued, obliged Huyghens to admit that Gregory had succeeded in proving the impossibility of what is called the indefinite quadrature of the circle, by which is meant the finding of a method of squaring any given sector of the circle whatsoever. But since it is well known that there are curves, particular portions of which may be squared, this may happen in the case of the circle. Thus it might be possible to give a geometrical rule for squaring the whole circle, even though the rule would not apply to every given sector. The proposition which Gregory imagines himself to prove, is that no sector of a circle can have to the circumscribed polygon a ratio expressible by a finite number of algebraical terms. The consequence of this, if established, must be drawn as follows:—Since geometry allows the use of nothing but definite circles and straight lines, a straight line equal to the circle in length (which being found, the whole difficulty is overcome) must be ascertained, if at all, by a construction in which points are successively determined by the intersections of straight lines or circles, or a straight line and a circle. The most complicated construction in Euclid may, if we begin from the first principles, be reduced to the determination of a succession of points in this manner. Now, in the most complicated case of the intersection of two circles of given or found radii and centres, the points of intersection may be determined by formulæ derived from the roots of an equation not exceeding the second degree, the roots of which can be expressed in a finite form: the two ends of the line equal to the circle could therefore be assigned in a finite form, and hence the length itself. And the area of any polygon (whose arcs are obtained by continual bisection) described about a given circle could also be expressed in a finite form, from which (the area of the circle being expressible by means of its circumference) the ratio of the area to that of the circumscribed polygon would also be expressible. But if Gregory's proposition be true, this area cannot be expressed in a finite form; neither then can any construction allowable in geometry attain the circumference of a circle.

The indefinite quadrature was shown to be impossible by Newton (Principia, book i., lemma 28), in a manner which lies open to solid objection; we shall not therefore produce this proof. In fact, it seems as difficult to induce geometers to agree in any proof of the impossibility of the indefinite quadrature, as others to leave off trying their powers upon what geometers themselves have ceased to attempt.

Montucla has given a tolerable list of those who have signalised themselves by attempting this problem without the requisite preliminary of studying geometry; if preliminary that may be called, which would have made them give up the attempt. We shall presently mention some of them; but first we have a list of those who were, most of them mathematicians, or, if not, known in other things. "Only prove to me that it is impossible," said some one, "and I will set about it immediately," and such seems to have been the general feeling of the quadrators, as Montucla calls them. They existed in crowds in the time of Archimedes; and the race is not yet extinct. One Bryso, a Greek, heads the list: he made the circle a mean proportional between the inscribed and circumscribed squares, which happens to be the content of the inscribed octagon. Next we have Cardinal Cusa, Orontius Fineus, and Simon à Quercu, or Duchesne, already mentioned. At the time when the problem really was of practical importance, every quadrator raised up an opposing mathematician; and the quadrature was sometimes so ingenious, and so near the truth, that it could only be opposed by new approximations to the truth. Thus Cusa was met by Regiomontanus, Orontius by Buteo and Nonius, and Duchesne by Peter Metius, who (it is said) was compelled to discover the very close approximation we have given under his name by that of Archimedes being insufficient to expose Duchesne. But independently of what we have already said about Metius, it is not true that Duchesne's quadrature required any new accuracy of limits to expose it. He produced 3·14660 . . . : and Archimedes had already shown that 3·14285 . . . . was too great. Quadrators whose results forced further investigation were of use, and if some of them would now arise, no one would object to fallacies so ingenious that new truths must be discovered to oppose them. The celebrated Joseph Scaliger, a mere tyro in geometry, tried his hand on this and other problems in 1592, and was met by Vieta, Adrianus Romanus, and Clavius. Longomontanus, the astronomer (refuted by Pell), J. B. Porta, and Hobbes (refuted by Wallis), are three names well known in other pursuits who must go down to posterity as having had distinguished success in false quadrature. The works of the last against geometry and geometers were the consequence of the mortification he felt at not having been admitted to have succeeded in his attempt. Before his time however, Gregory St. Vincent, an acute mathematician (to whom is due the discovery of the connection between the hyperbolic area and logarithms), had made the most elaborate attempt which ever was published, in his work on the quadrature of the circle (Antwerp, 1647). Such a challenger raised up Des Cartes, Roberval, Huyghens, and Léotaud, who soon despatched him.

As yet we have mentioned only mathematicians, or men of eminence in something: but we have also the Spaniard Falcon (1589), who dialogues with the circle in verse: Gephirauder and Alphonso de Molina, who attribute their discovery to inspiration; the latter overturns Euclid, and found another who was willing to admit his discoveries and translate them into Latin. A merchant in Rochelle, De la Leu, not only found out the problem by inspiration, but showed that the conversion of Jews, Turks, and Pagans depended upon it. Montucla gives some account of several other visionaries, the chief of whom is one Cluver, who found that the problem depended upon another, namely, "Construere mundum divinæ menti analogum," which, if it be translateable, is, "to make a world analogous to the divine mind." He also mentions Richard White, an English Jesuit, who stands out among the solvers of the problem as the only one who ever was convinced of his error. The writer of this article once pointed out the example of White to another Roman Catholic clergyman, who had come from South America to England, to publish a quadrature of the circle. The party addressed seemed struck by the instance, and promised to study more geometry before he proceeded further; in a little while however he relapsed, and his work was advertised, and, we believe, published.

---

* The following was the addition left by him, and printed by the editor of the second edition: "Après avoir réfléchi encore plus attentivement sur les raisonnements de Gregory, il me paraît avoir eu raison d'en déduire l'impossibilité de la quadrature même définie du cercle." For ourselves, we left off unable to dispute, but feeling the insecurity which attaches to almost all negative proofs. We thought it as convincing as Abel's proof of the impossibility of algebraic solution of the fifth degree, as that proof stood in Abel's own memoir.

After the time of Newton, and the abundant means which were then introduced to complete the quadrature, if such a thing were possible, persons versed in mathematics seem to have dropped the attempt, and the reign of the quadrators by instinct commences. It is true that a serious diversion was made by the theory of gravitation, which drew off against itself many of those who should have been quadrators; but enough remained to furnish a tolerable list.

That of Montucla contains principally Frenchmen, though had the history of mathematics been written by an Englishman, he could have produced as great a number in this country. One Mathulon, in 1728, promised in print 1000 crowns to any one who should convict his solution of error, and was actually sentenced by the courts to pay the sum to the Hôtel Dieu at Lyon, to which charity Nicole, the exposer, made over his claim. One Sullamar (as Montucla spells it), an Englishman, solved the problem by means of the number of the beast, 666, in the year 1750; a M. de Causans, in 1753, found it by cutting a piece of turf, and deduced from it the doctrines of original sin and of the Trinity. He offered to bet 300,000 francs on the correctness of his process, and deposited 10,000, which were claimed by several persons, and among others by a young lady, who brought an action for them: but the bet was declared void by the courts. Many more cases might be added; it is however enough to say that this problem is now never attempted (in print at least), except by those who are either altogether ignorant of mathematics, or add a most undue opinion of themselves to an acquaintance with only the elements. Since 1755, the Academy of Sciences has refused to examine any pretended solution; and the Royal Society in this country came to the same resolution a few years afterwards. In the announcement of their determination, the French Academy, without pronouncing any dictum upon the problem, stated that in a period of seventy years, those who had brought forward quadratures had been persons who did not know the nature of the difficulty of the problem. An experience of about half that time has satisfied us that the same thing may be said of our own day: and with this addition, that whereas the speculators who came before the Academy seem for the most part to have had an idea that their chance, if any, lay in the *geometrical* quadrature, the squarers of our time, in nine cases out of ten, announce the *arithmetical* quadrature, which has been proved to be impossible.

A few words may serve to prevent some one from making an attempt upon this enchanted castle, as it is supposed to be. When the difficulty first began to be noticed, the circle stood alone among curves; and so remarkable a distinction between this, the only curve then considered, and rectilinear figures, the only other figures then considered, could not but excite curiosity. Our position is now changed; not only does the now well recognised distinction of commensurable and incommensurable prevent the circle from presenting anything peculiar to itself, but the curve is only one among an infinitely great number, many of which have been investigated and their properties examined. Consequently, with reference to the present state of mathematics, the problem analogous to that of squaring the circle is, "Given any curve whatsoever, to find its area." Now if the ingenuity which is guided by the love of investigating hidden things, should desire a field for its exertions, let it leave that of the circle, which has been cropped until it will yield no more, and, first acquiring sufficient mathematical knowledge, let it spend its force upon some one of the many real difficulties which abound, both in the pure and mixed sciences: let it investigate the meaning of divergent series for example, in all their varieties, or endeavour to extend the theory of discontinuous expressions, or solve the equations of motion of the solar system by some other method than that of series. For one point that should strike the lover of the marvellous in the quadrature of the circle, there are hundreds in the above-named subjects which surprise the mathematician, however little he may possess that quality. Moreover, in like manner as the quadrature of the circle was at one time, in the hands of Wallis, Newton, &c., a road to results which, though they did not attain their end, yet answered many other purposes; so the efforts of the inquisitive on the actual difficulties of our own day may also end in the promotion of science of every kind, if begun in knowledge and directed by system. We owe the binomial theorem, now one of the most important results of algebra, indirectly to the learned attempts of Wallis upon the quadrature of the circle, at a time when such attempts were in season: and we might reasonably hope for collateral successes something like those resulting from the labours of Wallis, if those (not a few) whose minds compel them to inquiry into the curious, would but furnish themselves with a guide before they set out on their travels.

This problem still engages attention: and persons are found to believe that they have attained even the arithmetical quadrature. And it is a peculiarity of this well-worn old problem, that it catches the fancy of those who have not even attended to common geometry, and frequently makes them think that the riddle is reserved for *them* to read. And the reason is, that they treat it as a riddle: a thing to be thought out by some sudden stroke of mother-wit. They do not know that there are thousands of problems of the same kind in everything but notoriety. Thirty years ago, when the 'Penny Magazine' was young, it contained an article on this subject which might have been thought sufficient at least to establish the fact of a difficulty. A man of high rank and great wealth, who had probably never opened a book of geometry since his school days, if even then, happened to read this article, was caught, and in five minutes produced an idea which he thought so likely to be the solution of the enigma, as he would have it to be, that he forwarded it to the secretary of the Useful Knowledge Society, for transmission to the author of the article.

It has been stated in foreign newspapers within these few years that the British government does offer, and always has offered, a large reward for the solution of this problem. This, we need hardly say, is a complete mistake: the government never at any time offered one farthing for the quadrature of the circle. Some years ago, a labouring man from the country came to town with a quadrature, and addressed a letter to the Lord Chancellor, stating his claim, and desiring his lordship to hand over forthwith 100,000*l.*, being the sum due from government for the discovery, as per proclamation: this letter we saw. The only problem for the solution of which any reward was at any time offered, was the practical mode of finding longitude: and even this offer is now retracted; rewards having been, in fact, received by several persons. Should this article fall into the hands of any, at home or abroad, who are working at any mathematical or astronomical difficulty under the impression that our government is pledged to remunerate them in case of success, they may rest assured that their information is incorrect, and that they will find it to be so on inquiry. The only person we know of who states definitely what the reward is, and by whom offered, is Nicolas Ericius, in a tract on the quadrature "Fundamentalis figura geometrica . . . ." Copenhagen, 1755. The author states, as known to all, that on the 2nd of June, 1747, the Royal Society of London publicly advertised a reward of 30,000*l.* for the quadrature of the circle and the discovery of the true nature of the magnet, over and above some previously offered sum, the amount of which is not stated. It is needless to say that the archives of the Royal Society contain no account of any offer of the kind.

Persons who are not acquainted with the subject are puzzled by one consideration, which we admit is calculated to have weight. The quadrators appeal to great discoveries which have at last been recognised, though their promulgators were at first treated with contempt. We pass over the last part of the assertion with the remark that Copernicus, Galileo, Tycho Brahé, Harvey, &c., were never treated with *contempt:* some were opposed, some were persecuted, and all were ridiculed by a section of their opponents; for ridicule is a constituent of all opposition whatsoever, though not from every opponent. But those with whom Copernicus, &c., came in contact, whether in person or in book, showed amply that they knew what manner of men they had to deal with. The more important point is the following. Invention in mechanics may have been sometimes attained—not very often—by men who were ignorant of the doings of their predecessors. But discovery in matters of speculation—that is, conquest over old and tried difficulties—has never, that we have read of, been reached by any one whose mind had not been trained by study of previous speculation. All the men we have mentioned, and all of their stamp that we know of, were *learned* men, acquainted with the history of the subject they were destined to advance, and practised in its methods: they had all shown their power over what *was* known, before they presented themselves as the promulgators of what *was not.* The squarer of the circle, therefore, may be asked to show proof of his acquaintance with the previous history of the subject: any one who really does this would, even now, meet with some attention. But the general run of circle-squarers are as ignorant of the past as the future will be of them.

Again, we have to meet the very plausible objection, that many difficulties have been overcome at last: why not then the quadrature of the circle? The answer is easy. The difficulties which have been overcome at last have been overcome by the discovery of new means, and the introduction of new powers; but our problem is to square the circle with the *old allowance of means:* Euclid's postulates and nothing more. We cannot remember an instance in which a question to be solved by a *definite method* was tried for centuries by the best heads, and answered at last, *by that method,* after thousands of complete failures.

QUADRATURES, METHOD OF.

The method of quadratures derives its name from its earliest application, that of finding the areas of curves, which was always called their quadrature, as being the arithmetical process by which, when exact, squares equal to them might be found. And since the AREA of a curve can always be found when $\int y dx$ can be found, this term has also been applied to the determination of the definite values of integrals by approximation. We shall first complete the reference in OFFSET. An area being bounded by a curve, a part of the axis, and two extreme ordinates, if the base on the axis be divided into any number of equal parts by ordinates (offsets), the chords which join the ends of successive offsets, if substituted for the arcs of the curve, will give very nearly the same area. And this area is found by adding half the first and last offset to the sum of all the intermediates, and multiplying by the common base. This is the old surveyor's rule. Thomas Simpson gave one of more exactness, by drawing a parabola, of axis perpendicular to the base, through the first, second, and third points, another through the third, fourth, and fifth, and so on, the number of equal parts being even. The approximate area is then found by adding to the first and last offset twice the sum of all the other odd ones and four times the sum of all the even ones, and multiplying the sum so obtained by the third part of the common base, or smallest subdivision of the whole base. The following method gives any required amount of approximation. Any integral [INTEGRATION] can be found approximately by a summation, the limit of which is the exact value: thus we could determine $\int y\,dx$ from $x=a$ to $x=a+h$ by dividing h into a large number, n, of equal parts, and actually summing

$$a\cdot\frac{h}{n} + \left(a+\frac{h}{n}\right)\frac{h}{n} + \left(a+2\frac{h}{n}\right)\frac{h}{n} + \ldots\ldots + \left(a+n\frac{h}{n}\right)\frac{h}{n}$$

but the special object of that which is called *the* method of quadratures is the perfection of this method of quadratures (which is either very inexact or very tedious) by subsequent corrections, which are most readily derived from such mathematical considerations as are described in the article OPERATION. The theorem on which it is founded may be seen in p. 313 of the 'Differential Calculus,' in the 'Library of Useful Knowledge:' exhibited in the best form for practical use, it is as follows: –

Let $\int y\,dx$ be required to be found from $x=a$ to $x=a+h$: divide h into n equal parts, and let $A_0, A_1, A_2 \ldots\ldots A_n$ be the values of y corresponding to the following values of x, namely, a, $a+\frac{h}{n}$, $a+2\frac{h}{n}$, $\ldots$ $a+n\frac{h}{n}$ (or $a+h$). Compute

$$s=(A_0+A_1+A_2+\ldots\ldots+A_n)\frac{h}{n}$$

And, writing down A_0, A_1, &c., as below, take their differences. [DIFFERENCE.]

$$\begin{array}{c}
A_0 \quad A_1 \quad A_2 \quad A_3 \ \ldots\ldots\ldots\ldots \ A_{n-3} \quad A_{n-2} \quad A_{n-1} \quad A_n \\
\Delta A_0 \ \Delta A_1 \ \Delta A_2 \ \ldots\ldots\ldots\ldots \ \Delta A_{n-3} \ \Delta A_{n-2} \ \Delta A_{n-1} \\
\Delta^2 A_0 \ \Delta^2 A_1 \ \ldots\ldots\ldots\ldots\ldots \ \Delta^2 A_{n-3} \ \Delta^2 A_{n-2} \\
\Delta^3 A_0 \qquad \ldots\ldots\ldots\ldots \qquad \Delta^3 A_{n-3}
\end{array}$$

up to the fifth differences, which will be generally sufficient. Then the value of $\int y\,dx$ from $x=a$ to $x=a+h$ is as follows, very nearly :—

$$s-\frac{1}{2}\frac{h}{n}(A_n+A_0)-\frac{1}{12}\frac{h}{n}(\Delta A_{n-1}-\Delta A_0)-$$
$$\frac{1}{24}\frac{h}{n}(\Delta^2 A_{n-2}+\Delta^2 A_0)-\frac{19}{720}\frac{h}{n}(\Delta^3 A_{n-3}-\Delta^3 A_0)-$$
$$\frac{3}{160}\frac{h}{n}(\Delta^4 A_{n-4}+\Delta^4 A_0)-\frac{863}{60480}\frac{h}{n}(\Delta^5 A_{n-5}-\Delta^5 A_0)$$

For example, let the integral required be $\int\frac{dx}{x}$ from $x=9$ to $x=13$ (we take purposely a case in which verification is easy.) Here $a=9$, $h=4$, $y=1:x$. Divide the interval 4 into ten equal parts, so that $h:n=\cdot4$. We have then 9, 9·4, 9·8, ... 12·6, 13, for the eleven values of x, and writing down their reciprocals, and taking their differences, we have

	A =	ΔA = −·00	Δ²A = +·000	Δ³A = −·0000	Δ⁴A = +·00000	Δ⁵A = −·00000

$$\text{Approximate value of } \int_9^{13}\frac{dx}{x} = \cdot36772479$$

The same result, found by common methods, is hyp. log. 13 – hyp. log. 9, or 2·56494936 – 2·19722458, or ·36772478: so that the preceding method is in this case more than correct to seven figures by use of four differences.

This method of quadratures is the mathematician's last resource when all others fail or are still longer. In most of the cases in which it is absolutely requisite, the calculation of the values of y is the most tedious part of the operation. When the limits are very different, it is generally requisite to divide their interval into several parts, and to make the integrations through the several parts separately. For an inverse process see SUMMATION.

QUADRICHLORACETAMIDE, or *Chloracetamic acid* $\left(C_4HCl_4NO_2 = N\begin{cases}H\\ Cl\\ C_4Cl_3O_2\end{cases}\right)$, is a product of the action of chlorine upon trichloracetamide. It occurs in colourless, inodorous, acicular prisms, of disagreeable taste.

QUADRICHLOROBUTYRIC ACID. [BUTYRIC ACID.]

QUÆSTOR (from *quæro*: "*qui conquireret publicas pecunias et maleficia*," Varro, 'De Ling. Lat.,' iv. 14) is a name which was common to two distinct classes of officers at Rome, who were only distinguished from each other by different attributes: the name of one class was *quæstores parricidii*; that of the other, *quæstores classici*.

It is said by some that the office of *quæstores parricidii* existed even in the reigns of Romulus and Numa. Livy (i. 26) and Tacitus ('Annal.,' xi. 22) think that they were appointed by the kings; but it is more probable that the kings only proposed the candidates, and that they were appointed by the populus. (Ulpian, 'De offic. Quæst.,' 'Dig.,' i. 13.) That the office existed in the reign of Tullus Hostilius is certain, and the general opinion among the Romans was that it was instituted by that king. After the establishment of the republic, the two quæstores parricidii continued to be elected in the comitia of the curies, on the presentation of the consuls, as they were before on that of the kings: but they were now regularly elected every year, whereas before they had only been appointed in cases of emergency. After the decemvirate, they were elected by the centuries. At the time of the Licinian law one part of their functions was swallowed up by the office of the triumviri capitales, while the rest were embodied in the offices of the curule ædiles and the tribunes.

The *quæstores parricidii*, according to Niebuhr, were the same as the *duumviri perduellionis*, but Walter ('Gesch. des Röm. Rechts,' p. 855) has adduced a number of passages which seem clearly to prove that the *quæstores parricidii* must be distinguished from the *duumviri perduellionis*, who continued to be elected to the end of the republic, and were real judges in cases of perduellio. The quæstores, on the other hand, were a kind of public accusers, who conducted the accusation and carried the sentence into execution. (Festus, s. v. 'Parici;' Dionys. Hal., viii. 78.)

The *quæstores classici* had the superintendence of the public treasury, and are said to have been instituted by Valerius Publicola, who gave the right of electing them to the populus, though Wachsmuth ('Geschichte des Römisches Staats') contends that there was only one kind of quæstor. At first they were only two in number, and in the year 421 B.C. their number was doubled (Liv., iv. 43.) and part of them were to be plebeians, but this was not the case until ten years afterwards, when three out of the four quæstores were plebeians. (Livy, iv. 43, 54.) From the time that four quæstores were elected, two accompanied the consuls into the field, while the two others remained in the city (quæstores urbani). After the Romans had made themselves masters of all Italy (489 B.C.), the number of quæstores was again doubled, so that there were now eight of them (Liv., 'Epit.,' lib. xv.), for the administration of the financial affairs in the city, in the army, in Italy, and the province of Sicily. One of them, who resided at Ostia, had also to provide the city with corn. (Cic., 'pro Sext.,' 17.) Sulla in his dictatorship raised their number to twenty, and Cæsar to forty. (Tacit., 'Annal.,' l. c.; Dion Cass., xliii. 47, 51.) During the time of the emperors their number varied. The two quæstores urbani, down to the time of Julius Cæsar, had the administration of the public treasury; they registered the revenue and expenditure of the republic (Ascon. Ped. on Cic., 'in Verr.,' ii. l. p. 158, ed. Orelli; Plut., 'Cat. Min.,' 17, 18), received the money due to the state, and made the payments sanctioned by the senate. They had also to receive and take under their especial protection all foreign ambassadors, and those strangers who were connected with the state by ties of public hospitality; finally they had the care of the funerals and monuments which the senate decreed as distinctions for men of great merit (Plut., 'Quæst. Rom.,' 43; Val. Max., v. 1, 1; Cic., 'pro Flacco,' 18): they kept in the treasury the books in which the senatus consulta were copied, until Augustus also entrusted them with the keeping of the original documents. (Dion Cass., liv. 36.) Julius Cæsar transferred the administration of the treasury from the quæstores to two ædiles. (Dion Cass., xliii. 47.)

The military quæstores who accompanied the consuls into the field (Cic., 'in Verr.,' ii. 1. 15) had the charge of the money with which the war was carried on, distributed among the soldiers their provisions and pay, and superintended the sale of the booty, the produce of which was either divided among the soldiers or lodged in the public treasury. (Livy, iv. 53.) They had however to give in an account of all their proceedings to the treasury. (Cic., 'in Verr.,' ii. l. 14; and Ascon. Ped., p. 167, ed. Orelli.)

With the extension of the Roman empire, a greater number of quæstores was required for the financial administration of the conquered countries and the provinces, and it was chiefly owing to this that their number increased in proportion as the empire became greater. The prætor was therefore usually accompanied in his province by a quæstor, who had the whole financial department under his control, but was, like the other quæstores, accountable to the treasury; in case of his death, the prætor appointed a pro-quæstor in his stead. (Cic., 'in Verr.,' ii. l. 15.) When the prætor was absent from his province, the quæstor usually supplied his place, and was then attended by lictors. (Cic., 'ad Fam.,' ii. 15; 'pro Planc.,' 41.) There seems to be no doubt that the quæstors at all times, after the year of their office was over, had a right to take their seat in the senate; of Sulla it is expressly said that he raised their number to twenty, for the purpose of filling up the vacancies in the senate.

In the time of the emperors we have mention of some quæstors who bore the title of Candidati principis, and who were not sent into provinces, but had only to read in the senate the communications which the emperor had to make to that assembly. From the time of the emperor Claudius it became customary for quæstores, on entering upon their office, to give gladiatorial spectacles to the people, and accordingly none but the wealthiest Romans could aspire to the office.

The quæstores, in the provinces of the Populus Romanus, had the jurisdictio of the curule ædiles, and consequently the right of promulgating edicts. No edicts were promulgated in the provinces of the Cæsar. (Gaius, i. 6.)

QUAKERS, the name first given "in scorn," and since habitually, to the sect of Christians who call themselves the "Society of Friends." [Fox, George, in Biog. Div.]

Origin.—The founder, or rather the first member of this society was George Fox, who towards the middle of the 17th century, after long wanderings about the country and much spiritual conflict and inquiry into the merits of the sects then raging against each other in England, separated himself from all, feeling that "none could speak to his condition." By degrees his religious opinions assumed a distinct form, and in the year 1647, when he was 23 years of age, he commenced his ministry by preaching at Dukinfield near Manchester. In a short time the number of believers in his doctrines increased; in 1648 large meetings attended his ministry in Nottinghamshire, and, notwithstanding cruel persecution, the society spread from the poor and uninstructed to many of the more opulent and educated classes.

It is not our intention to describe the process by which George Fox was led to adopt his peculiar opinions, or the course of conduct which these induced him, whilst yet a very young man, to pursue. Such a narrative might cast on the sect an air of extravagance, which belongs less to this body in particular than to the period of religious excitement in which it had its rise. Notwithstanding instances of indiscretion or enthusiasm in some of its first members, the early history of the society is full of examples of undaunted courage in passive and ultimately successful resistance to oppression.

Tenets.—The Society of Friends have no articles of creed, subscription to which is required of their members. Their principal tenets may however be gathered from the writings of George Fox, William Penn, and Robert Barclay, and their other approved authors, and from the minutes and epistles issued by their yearly meeting in London to the subordinate meetings.

They believe that it is the prerogative of God alone to declare himself to man; and therefore they prefer expressing their religious opinions in the language of Holy Scripture. In full accordance with these sacred writings, they have ever believed that there is one God and Father of all, of whom are all things; that there is one Lord Jesus Christ, by whom all things were made, who was glorified with the Father before the world was, who is over all, God blessed for ever; that there is one Holy Spirit, the promise of the Father and the Son, the Leader, Sanctifier, and Comforter of his people: and that these three are one God. Whilst objecting to scholastic terms and distinctions, and to all attempts to be wise in the deep things of God, beyond what He has plainly revealed, they have ever professed their belief in the real manhood as well as the true deity of our Lord and Saviour Jesus Christ; that the Word which was in the beginning with God, and was God, was made flesh and dwelt amongst men. They maintain that man in the fall is separated and alienated in his nature from God; that all have sinned and come short of the glory of God, and are therefore exposed to divine wrath; and that it is solely through the mercy of God in Christ Jesus that any are brought into reconciliation with him; receiving remission of sins through faith in the one propitiatory offering of the Lamb of God, and sanctification of heart through the influences of the Holy Spirit. They believe the Holy Scriptures to be given by inspiration of God, and to be profitable for doctrine, for reproof, for correction, for instruction in righteousness; and they have always professed their entire readiness that their tenets and practices should be tried thereby

But that which may be regarded as the doctrine mainly distinguishing them from other Christians, is what they apprehend to be a fuller recognition both of the universality and of the teaching of the Holy Spirit. They believe that the light of the spirit of Christ does in measure enlighten every man that cometh into the world; that the effects of the death of Christ are coextensive with those of Adam's transgression, according to the declaration of the Apostle, "As in Adam all die, even so in Christ shall all be made alive;" and, as a consequence hereof, that even those who have not the outward knowledge of the Gospel history may, by giving heed to their measure of this light, become partakers of that salvation which comes by Jesus Christ.

They moreover believe that the guidance of the Holy Spirit is to be experienced by every sincere believer in Christ, in reference both to his religious duties and to his daily walk in life,—that to be guided by the Spirit is the practical application of the Christian religion. They also maintain that this manifestation of the Spirit, given to every man to profit withal, is the only essential qualification of the Christian for service in the church, and is independent of human choice or appointment. They hold it to be the prerogative of Christ to call and qualify by the Holy Spirit his servants to minister in word and doctrine, and that, as in the earliest period of the Christian church, this Spirit was poured upon servants and upon handmaidens, so he continues to call from *women* as well as from men, from the young and from the old, from the unlearned and from the poor, from the wise and from the rich, those whom he commissions to declare unto others the way of salvation. As such have freely received the gift of the ministry, so are they freely to give without hire or bargaining, far less to use it as a trade to get money by. Hence they refuse the payment of tithes and all other ecclesiastical imposts. They believe that the true worship of God is offered in the inward and immediate moving and drawing of his own Spirit; and that all other worship, beginning and ending in man's pleasure, ought to be rejected. Hence they abstain from the use of all prescribed forms of prayer, and refuse to observe appointed days of thanksgiving, or of fasting and humiliation. They believe that as all the types and shadows and ordinances of the law were fulfilled in Christ, so he established no new ordinances to be administered or to be observed in his church, that his baptism is that of the Holy Ghost and of fire, that he himself is the bread of life, and that the communion of his body and blood is inward and spiritual, and that in thus partaking of the substance, the figures are no longer needed. They assert that as God hath assumed to himself the dominion of conscience, all punishment for conscience sake is therefore contrary to the truth; provided that no man under the pretence of conscience prejudice his neighbour. They believe that true religion delivers man from the spirit and vain conversation of this world, and leads him to inward communion with God; and that hence all foolish and superstitious formalities and all frivolous recreations ought to be rejected: thus all public rejoicings are disapproved of.

Friends deem the taking of all oaths unlawful, and much of their sufferings arose from the firmness with which in former days they refused the oaths often wantonly tendered to them. They believe too that all wars and fightings are inconsistent with pure Christianity, and they refuse all participation directly or indirectly in them. They believe marriage to be a divine ordinance, but in their marriages they do not use the intervention of a minister, for whose interference they allege that there is no Scripture warrant. When any of the Society intend to marry, they acquaint their respective men's and women's meetings of their intentions, and the necessary inquiries having been made as to the consent of parents, the freedom of the parties from all previous engagements, and, if the woman is a widow with children, as to the security of a due provision for these, the parties in a public meeting for worship solemnly take each other in marriage, and a certificate of the fact is given to them. Friends abstain from all pomp in the burial of their dead and from the use of mourning apparel or of grave-stones. They do not use the heathen names of the days or months, but designate them by their numbers; and they object to address an individual in the plural number, or by his title of courtesy, or by any designation which they consider as either inconsistent with Christian truthfulness, or as irreverent or merely complimentary; but they have no scruple against the use of the simple names of dignity or office.

Discipline.—The discipline of the society was at least indicated and to a great extent established by George Fox with much foresight; for notwithstanding the great increase of the body and the altered circumstances of the times, the system has been found adequate to the protection and the government of the society.

The members of one or more congregations (according to their size) hold monthly meetings for looking to the orderly conversation of the members, for taking care of their poor (a duty which the society rigidly fulfils to the superseding of all parochial relief), for regulating the proceedings in relation to marriage, and for other matters affecting the well-being of the body.

There are quarterly meetings throughout the nation, to which representatives are sent from the subordinate monthly meetings. There are also monthly and quarterly meetings of women Friends similarly constituted.

There are meetings for worship on Sunday, and in the forenoon of one other day in the week. The epistle from the yearly meeting in 1675 exhorts Friends not to decline, forsake, or remove their public assemblies because of times of suffering; for such practices are not consistent with the nobility of truth.

Finally, there is a yearly meeting of representatives from all churches of the society throughout Great Britain and Ireland. This meeting is held in London on the Wednesday after the third Sunday in May, and remains sitting many days. It receives reports of the state of the particular churches, and it issues to them a general epistle. A similar representative body or yearly meeting of women Friends is held at the same time for the general supervision of the religious state of those of their own sex, but they have no power to make rules for the government of the body. During the intervals of the yearly meeting, the general business of the society is conducted by a meeting termed the Meeting for Sufferings, which is a carefully selected standing committee of the yearly meeting. There is a general fund belonging to the society, called the national stock; it is formed by the voluntary contributions of members, and it is applied to the publication of religious works, the expenses attending applications for legislative relief in cases of suffering, the payment of the expenses of ministers travelling in foreign parts out of the limits of any meeting, and other public objects of the society.

Whilst it is the duty of the individual members of the society generally to watch over one another in love, this duty is more especially confided to certain officers of each sex in the respective meetings, who are called overseers, and who, whenever any case of delinquency comes to their knowledge, visit the individual privately, and labour with him in tenderness with a view to his restoration; but if these efforts prove unavailing, they are to bring the case to the monthly meeting, which appoints a committee to exercise further care in reference to it; and if all attempts at reclaiming the offender should fail, he is disowned as a member of the society by a document issued by the monthly meeting and signed by its clerk.

There are many wise provisions made by the society for exercising care over those who believe themselves called to the work of the ministry. This care is more especially entrusted to the elders, who are persons chosen for their spiritual discernment, and from having given evidence by their fruits of the soundness of their faith. The eventual recognition or acknowledgment of ministers as such rests however with the monthly meeting at large, including all the men and women members of the congregation. Monthly meetings are cautioned not hastily to give certificates of competence to those who desire to travel in the ministry; but to take care that these are well approved at home, are of sound doctrine, of good conversation, and in unity with their own meetings.

This notice of the Society of Friends ought not to be closed without honourable mention of their constant efforts in the cause of humanity. The Lancasterian system of instruction has found among Friends some of its most zealous supporters; they also early opposed the slave trade, and in 1761 members engaged in the slave-trade were disowned. Latterly there has been a growing tendency to modify the distinctive peculiarities of dress and speech, and the desire for a certain amount of conformity to the innocuous habits of ordinary society has received the formal sanction of the annual meeting. For some time there have been symptoms of a decrease of numbers of the sect, and in 1859 prizes were offered for the best essay on the causes of such decline and the means of remedying them.

(‘Rules of Discipline for the Religious Society of Friends,’ London, 1834; Sewel's ‘History of the People called Quakers,’ London, 1834; Barclay's ‘Apology,’ (the edition used for this article is that of 1701, London); and ‘Memoir of the Life of George Fox,’ 1839; also the articles Fox, Barclay, Penn, and Gurney, in the Biog. Div.)

QUALITY (from the Latin *qualis*), in the common acceptation, comprises all attributes that can be given to a thing, with the exception of those of magnitude and quantity, and it matters not whether the attributes are essential to the thing or merely accidental. But in speaking of the qualities of things, we chiefly consider those by which they are distinct from other and similar things. This circumstance accounts for some expressions, such as "a man or a person of quality," in which the word quality is used synonymously with rank, as *the* quality by which in aristocratical countries one class of men is distinguished from all others.

Among the ten categories or fundamental notions of the philosophy of Aristotle, quality is the third; but Kant, who has reduced the ten categories of Aristotle to four, makes quality the second; and according to him it comprises the notions of existence, non-existence, and limitation; or of reality, negation, and limitation; that is to say, all things which come within the sphere of man's thought are, in the category of quality, either something or nothing, or something of which he can only say what it is not. In logic, affirmation and negation are the qualities of a *proposition*.

QUALITY OF ESTATES, QUANTITY OF ESTATES. [Property.]

QUANTITY. There is little here to add to what has been said in the article Magnitude, so far as the mathematical notion is concerned. The quantity of anything is the answer to *quantus?* (how much?) and the considerations under Ratio are necessary to the precise answer. Mr. Mill, in his ‘Elements of the Human Mind,’ has invented the word *tantity*, since *quantus* (how much) is answered by *tantus* (so much); and he therefore uses quantity and tantity as correlative words. But in truth the meaning of *quantity*, as generally received, does not refer to the question, but to the answer: so that the word *tantity*, if introduced, could only mean the same thing as quantity, unless the meaning of the latter word were changed. If any one were to propose that quantity should signify what it does at present, with the addition of a reference to seeking, requiring, or asking, and that tantity should involve the same notion, its object being considered as found, given, or determined, undoubtedly the proposition would be a good one, considered apart from the difficulty of altering established meanings. The word *quantuplicity*, as distinguished from quantity, means the answer to how *many times*, as distinguished from how much. [Ratio.]

The notion attached to the word quantity in the middle ages varied between two extremes. At one end it signified the abstract idea of that about which *quantus* can be asked: and in this sense it necessitated the startling maxim that "quantity does not admit of more and less." Thus we have not more right to say of a mile than of a foot that it is the proper subject of the question *quantus*, or has *quantitas*. At the other end, quantity was a "thing which is *per se* divisible into parts": thus making the quantity to be the thing from which the notion arises, which some called the *res quanta*. This idiom is common in all time; and it has sometimes created confusion, and that in every line of thought, from agriculture to logic. We should perfectly well understand what a person meant who said that he had bought a hundred-weight of sugar from Smith, and had sold *as much* to Jones, but not the *same quantity*: and we should also understand the charge of having made a blunder which might be brought against the speaker. But there is no blunder at all: the phrase has always been in use, and has lasted from the time of the schoolmen, of whom many defined *quantity* as being *res per se divisibilis in partes*. Blunder begins when a person confuses this old concrete sense with the modern one, in which *quantity* is the proper answer to *how much?* on a thing which admits of the notion of more and less.

Quantity admits another important division. In some quantities (now meaning *res quantæ*) we hold the parts in joint and separate existence at once, as in length, area, solidity, angle, time, number. In others we have not the separate perception of parts, though sensible of a whole which we are conscious might be more or less, Thus when we see a foot, we see the inches: but when we feel a pound, we do not feel the ounces. Some of the old writers say that it is essential to quantity to have *partes extra partes:* that is, to be of the first kind now under discussion. But they cannot help admitting quantities which do not satisfy this so-called essential condition. The truth seems to be that only in the fundamental notions of mathematics, space, time, and number, do we feel cognisant of the *separate* existence of parts in a whole by the same means which make us cognisant of the whole. In other things we learn by instruments, material or solely mental. We should never have divided *weight* into parts, if it had not been for the invention of the balance: nor *belief*, if it had not been for the calculus of probabilities, aided, in the first instance, by the definiteness of the cases which are on the cards or on the dice.

QUANTITY OF MATTER. [Mass.]

QUANTITY OF MOTION. [Momentum.]

QUARANTINE. Quarantine regulations are regulations chiefly of a restrictive nature, for the purpose of preventing the communication from one country to another of contagious diseases, by means of men, animals, goods, or letters. The origin of the term *quarantine* (which originally signified a period of forty days during which a person was subject to the regulations in question) is explained in the article Lazaretto. The period of forty days during which a widow entitled to dower can remain in her husband's mansion-house after his death is also called, in our law, the widow's quarantine. (Blackstone's ‘Commentaries,’ vol. ii.)

Quarantine regulations consist in the interruption of intercourse with the country in which a contagious disease is supposed to prevail, and in the employment of certain precautionary measures respecting men, animals, goods, and letters coming from or otherwise communicating with it. Men and animals are subjected to a probationary confinement, and goods and letters to a process of depuration, in order to ascertain that the contagious poison is not latent in the former; and to expel it, if it be present, in the latter. Quarantine regulations respecting *men* and *animals* are therefore founded on the assumption that the contagious poison, after having been taken into the constitution of a man or an animal, may remain dormant in it for a certain time, and that a seclusion of a certain duration is necessary, in order to allow the disease time to show itself, or to afford a certainty that the disease is not there. Quarantine regulations respecting *goods* and *letters* are founded on the assumption that the contagious poison may be contained in goods and letters, and transmitted from them so as to communicate the disease to men.

The country from which the introduction of a contagious disease is apprehended, may either be conterminous with the country which establishes the quarantine regulations, or may be divided from it by the sea. Accordingly quarantine lines may either be drawn round a coast, as is the case in France, Italy, and Greece, with respect to the Levant; or they may be drawn along a land frontier, as on the frontier between Austria and Servia and Wallachia.

The contagious diseases which quarantine regulations are intended to guard against are plague and yellow-fever, and latterly cholera. We are not aware whether small-pox has ever been made a subject of quarantine regulations; but this question is now of no practical moment, since vaccination has supplied a preventive of small-pox far more efficacious than any quarantine regulations could be.

The most important disease, with reference to quarantine regulations, is the *plague of the Levant;* and in practice, quarantine regulations are of little importance except with respect to the intercourse by land and sea with Turkey, Asia Minor, and Egypt, and some other of the Mohammedan countries bordering on the Mediterranean.

In the article PESTILENCE there is an explanation of the nature of the disease styled plague, which, although formerly prevalent over the whole of Europe, is now nearly confined to the Levant; and it is there stated that its symptoms, morbid changes, history, and mode of propagation, bear so close a resemblance to those of the malignant typhus of this country, that it is difficult to regard them otherwise than as different types of the same disease. It is also shown in the same article that the plague of the Levant appears to be generated by the same causes which generate typhus in this country, namely, filthy, crowded, and ill-ventilated dwellings, want of personal cleanliness, defective drainage, and insufficient or unwholesome food (Report of Dr. Arnott and Dr. Kay, in the Appendix to the 'Fourth Annual Report of the Poor-Law Commissioners,' p. 103), and that when the disease has been thus generated, it may, particularly under the influence of any of the causes which originally produced it, be communicated from one person to another. It appears likewise that its communication from one person to another is promoted not only by filth, want of ventilation, and the other usual accompaniments of squalid poverty, but also by certain atmospheric causes, such as a certain state of heat, moisture, &c., respecting which we are as yet imperfectly informed. The plague, therefore, is both epidemic and contagious; that is to say, it may either be generated by local causes, which simultaneously affect a large number of the inhabitants of a country, or it may be communicated directly from one person to another. Where a disease is both epidemic and contagious, it is difficult to determine what proportion of the cases of it are due to local causes and what proportion to contagion. The analogy of typhus in this country would lead us to believe that the number of cases of plague in the plague countries produced by contagion is small as compared with the number produced by local causes. The invisible nature of the ordinary causes of plague and other epidemic diseases, and the simultaneous seizure of many persons in the same district, the same street, or the same house, have naturally led to the belief that the disease is in every case communicated from one person to another; according to the fallacy ingeniously exposed by Dr. Radcliffe, who, on being asked his opinion respecting the contagiousness of epidemic diseases, answered: "If you and I are exposed to the rain, we shall both get wet; but it does not follow that we shall wet one another."

This view of the ordinary causes of plague is likewise confirmed by the undoubted fact which is adverted to in the article PESTILENCE, that the poor are the chief sufferers by it, and that it prevails most in the filthiest and worst quarters of towns. Dr. Patrick Russell, in writing of the plague at Aleppo in 1762, makes the following remarks:—"The villages appeared to suffer in a singular degree, owing perhaps to the structure of the huts and cottages, which are small, with few or no windows, and stand crowded together. In this they resemble the Keisarias within the city, which are inhabited by the lower class of people, and in which the contagion spreads also with great fury. The inhabitants of the city of the same class, but who live in districts where the houses are less connected, suffered more than the middling class possessing more airy habitations, but less than the Keisarias. The people of rank, or in higher offices, *notwithstanding the promiscuous crowds frequenting their palaces*, suffered least of all. Neither the governors of the city, the cadi, nor the nakeeb, and very few of the agas of superior rank, were themselves infected, though the plague had penetrated into most of their harems, and many of the pages and other attendants without doors were carried off by it. In these great harems, however, the contagion seldom spreads much; of perhaps about forty females, not more than four or five being infected. . . . Of all people, the Jews appear to have the strongest dread of the plague, a circumstance in one light rather fortunate, no place being more favourable to its propagation than the habitations of the lower class of that nation. The houses are small, or, if large, the different apartments are crowded with different families. Many of the houses are more than a story below the level of the street, in a condition half ruinous, dirty in the extreme, damp, and badly aired, from the nature of the situation: and the wretched inhabitants are clothed in rags. When one of them is taken ill, and known to have the plague, he is immediately abandoned to the care of an attendant, and the rest of the family seek refuge, if possible, at some distance. The families lodged in the other apartments, all not having it in their power to fly, are obliged to remain, but avoid approaching the chamber of the sick, and restrain their children from going into the court-yard. Thus pent up, they suffer all the inconveniences of the hot season in the midst of perpetual dread, till at length, what often happens, they also are attacked with the distemper. It was not without horror I descended into these dreary mansions." (Russell's 'Historical Journal of the Plague,' pp. 61-64.)

From the fact of the plague prevailing principally among the poor, and rarely attacking the rich, it may be inferred either that the plague is produced exclusively by the filth, crowding, and bad food to which the poor are subject; or that, if it be contagious, the contagion does not in general take effect upon the inhabitants of spacious and cleanly houses, who are clean in their persons, orderly in their habits, and have a sufficient supply of wholesome food. We see that diseases which appear to be contagious under nearly all circumstances prevail equally among the rich and poor, and that none of the physical advantages possessed by the rich afford any security against it. Thus, before the introduction of vaccination, small-pox was equally destructive to persons of all ranks in society; and the contagious diseases which attack children, as measles and hooping-cough, make no distinction between the children of the rich and the poor.

There seems to us to be no reasonable doubt that the plague is contagious—in other words, that it can be communicated directly from one person to another—provided there be circumstances favourable to its transmission. A quarantine for men may therefore be expedient for countries where the spread of the plague, supposing it to be introduced, is not improbable. The duration of this quarantine ought to depend upon the time during which the disease may be latent in a person who has taken it by contagion or otherwise.

Since the plague is a peculiarly malignant and destructive fever, and runs its course with a rapidity far greater than typhus, there seems a fair ground for concluding that its poison would not be long latent in the human body. The answers of the protomedico of Malta respecting the plague in Malta of 1813, state that "the periods at which the disease made its appearance in different individuals after communication were various. It was generally from the third to the sixth day; sometimes longer, even to the fourteenth day, but not later." (Dr. Maclean, 'On Epidemic and Pestilential Diseases,' vol. ii. p. 29.) M. Ségur Dupeyron, the secretary of the Council of Health in France, states, in his Report on Quarantine to the Minister of Commerce (May, 1834), that "the physicians who have made a close study of the plague are pretty generally of opinion that its poison cannot be latent in the human body more than fifteen days; and the cases of plague introduced into the lazarettoes confirm this opinion" (p. 48). We believe that the cases of plague which have in recent times occurred in the lazarettoes of Valletta, Marseille, and Leghorn have broken out either at sea or shortly after the ship's arrival. When the line of French steamers was first established, in 1837, between Marseille and the Levant, it was arranged that the steamers coming from the Levant should perform their quarantine at Marseille. But in consequence of several cases of plague having broken out on board the steamers before they could reach Marseille, the French government decided that they should perform their quarantine at the nearest practicable station, namely, Malta.

It is commonly assumed that actual or nearly actual contact is necessary in order to communicate the plague. "All measures against the plague (says M. de Ségur Dupeyron) are founded on the opinion that, except within a very small distance from the body, contact alone can give the disease. Consequently goods taken from ships with different bills of health are often placed in the same warehouse; and physicians who have visited plague patients, without having touched them, are not put in quarantine, and are permitted to go about immediately after their visit" (p. 76). We believe the idea that actual contact is necessary for the communication of the plague to be utterly erroneous; and we entertain no doubt that under circumstances favourable to its communication, such as filth, crowding, and want of ventilation, the poison of the plague might be introduced into the human body by inspiration through the lungs. We account for the escape of the physicians, guardians, and others, who come within a short distance of the plague-patients in lazarettoes, by the supposition that in the isolation, cleanliness, and good ventilation of a well-managed lazaretto, the contagion of the plague is exceedingly feeble.

With respect to the quarantine of animals, it may be remarked that, according to the belief commonly received in the Mediterranean, all living animals are capable of communicating the plague. Accordingly horses, asses, cattle, and sheep are placed in quarantine upon their importation. There is, we believe, an idea among the Franks resident in the plague countries, that the horse cannot communicate the poison of the plague, but that it is frequently communicated by other animals, especially by cats. (See Maclean, vol. i. p. 202) We suspect that there is no foundation for the notion that plague can be communicated by means of animals.

Goods carried in ships or by land are subject to quarantine, according as they belong to the class of susceptible or non-susceptible goods. Goods which are supposed to be capable of containing and transmitting the poison of the plague are called *susceptible.* Goods which are supposed to be incapable of containing and transmitting the poison of the plague are called *non-susceptible.* All animal substances, such as wool, silk, and leather, and many vegetable substances, such as cotton, linen, and paper, are deemed susceptible. On the other hand, wood, metals, and fruits are deemed non-susceptible. In Venice an intermediate class, subject to a half quarantine, is introduced between susceptible and non-susceptible goods (Ségur Dupeyron, p. 70); but this classification appears to be peculiar to the Austrian dominions. All susceptible goods are unladen in the lazaretto, and are there exposed to the air, in order to undergo a process of supposed depuration.

The grounds of the received distinction between susceptible and non-susceptible articles must, we conceive, be altogether fanciful, since we cannot discover any evidence that the plague has ever been communicated by merchandise. Whenever the plague has been introduced into the lazarettoes of the Mediterranean it has always been introduced by passengers or their clothes. (Ségur Dupeyron, pp. 45–48.) It may be added, that the persons employed in the process of depurating susceptible goods have never been known to catch the plague, which could scarcely have failed to be sometimes the case if the poison of the plague could be transmitted through goods. (See answer 28 of the Maltese protomedico, in Maclean, vol. ii. p. 31.) It seems to be likewise supposed that some substances are not only non-susceptible, but can even nullify the poison of the plague in susceptible articles. "At Trieste (says M. de Ségur Dupeyron) the juice of dried grapes is considered as a purifier; and consequently currants in susceptible wrappers are allowed to pass without the wrappers being subjected to any quarantine" (p. 72).

There appears, however, to be conclusive evidence that the clothes and bedding of plague patients have transmitted the plague. (Dupeyron, pp. 32-71.) We believe the danger of its transmission in this manner to be equal to the danger of its transmission by passengers.

We are not aware of any well-authenticated example of the transmission of plague by means of letters. Nevertheless as paper is considered susceptible, letters coming from and passing through the plague countries are opened and fumigated at the lazarettoes, a process which is often productive of mistakes, delays, and other inconveniences.

Every ship is furnished by the consul or other sanitary authority at the last port where it touched with an instrument, styled a bill of health, declaring the state of health in that country. If the ship brings a clean bill of health, the passengers and goods are not subject to any quarantine. If she brings a foul bill, they are subject to quarantines of different durations, according as the plague is known or only suspected to have existed in the country at the ship's departure. On account of the prevalence of plague in the countries upon the Levant, they are considered as permanently in a state of suspicion, and no ship sailing from any of them is considered to bring a clean bill. The periods of quarantine vary from two or three to forty days; the usual periods are from ten to twenty days.

For a description of the buildings in which passengers usually perform their quarantine, and in which goods are depurated, see LAZARETTO. The most spacious and best appointed lazarettoes in the Mediterranean are those at Malta and Marseille. To the statements contained in the article just referred to, we add the following curious description of a quarantine station on a land frontier, quoted from a manuscript journal in Murray's 'Handbook for Southern Germany,' p. 457:—"Outside Orsova, by the waterside, and near the ferry over the Danube, stands the Parlatorium, a wooden shed in which the market (skela) is held three times a week. On account of the quarantine regulations, the inhabitants of Servia and Wallachia are prevented coming in contact with the subjects of Austria, and dare not cross the frontier without an escort. The Austrian quarantine is five days for those who come out of Wallachia, and ten for those from Servia, increased to forty days in time of plague. The Wallachians, again, have a quarantine of five days against the Servians; so that none of the three parties can intermix for the purpose of buying or selling, nor can they touch each other's goods. On this account, the building where the market is held is divided by three partitions, breast high, behind which the dealers of the three nations are congregated. In an open space in the centre is a table, by the side of which the Austrian quarantine officers take their stand, aided and supported by a guard of soldiers with fire-arms and fixed bayonets to enforce order and obedience. Whenever a bargain is made, the money to be paid is handed to one of the attendants, who receives it in a long ladle, transfers it to a basin of vinegar, and, after washing it, passes it on to the opposite side. The goods to be purchased are placed within sight, and are immersed in a tub of water, or fumigated, when they happen to change owners. It is an amusing sight to see the process of bargaining thus carried on by three parties at the distance of several yards from each other, attended by the vociferation and gesticulation inseparable from such business. When the bartering is transacted, the Wallachians are escorted back to their own territory, as they had previously been in coming to the spot, by a guard of soldiers, and the Servians recross the river in their boats."

The institution of quarantine originated at Venice, in which city the expediency of some precautions against the introduction of the plague was suggested by its extensive commercial relations with the Levant. A separate hospital for persons attacked by the plague was established in an island near Venice, in 1403; and the system of isolating passengers and depurating goods appears to have been introduced there about 1485. The system thus established in Venice gradually spread to the other Christian countries in the Mediterranean, and has been adopted, to a greater or less extent, over all the civilised world.

Attempts have been made to modify the quarantine laws without success.

The reason why it is necessary for a nation to adapt its quarantine regulations to the received opinions upon the subject, is explained in the following extract from a paper respecting quarantine regulations in the Mediterranean, which was printed in the Malta 'Government Gazette" of the 19th December, 1838:—"The quarantine regulations of the English colonies in the Mediterranean cannot be changed by the simple will of the English government without producing inconveniences far greater than those arising from the existing system. If the English government should change the quarantine regulations of Malta and its other colonies in the Mediterranean without previously obtaining the approbation of the sanitary authorities of the neighbouring countries, the pratique granted in those colonies would not be received elsewhere; and all vessels coming from any of those colonies would be subjected to a quarantine of observation (from eight to fifteen days). The latter liability would attach to ships of the royal navy as well as to merchant vessels; so that no ship of war sailing from Malta could communicate with any part of France, Italy, or Austria, without being previously subjected to a quarantine of observation. Malta, in particular, would suffer most severely by being unable to give an effectual pratique to ships performing quarantine in the harbour of Valletta, and by subjecting all ships clearing out of that harbour to a quarantine of observation. Not only would its transit trade be almost completely destroyed, but it would lose its importance as a quarantine station. Its importance as a quarantine station is now daily growing, on account of the establishment of the French steamers to the Levant, and the use of the overland journey to India. It would, however, cease to be a quarantine station if its pratique was not received by the Board of Health at Marseille, and by the other sanitary authorities of the Mediterranean. In order, therefore, that the quarantine regulations of the English colonies in the Mediterranean might be safely altered, it would be necessary that the alterations should be made in concert with the governments of the neighbouring European countries."

The small states of Italy have been suspected (and, we fear, with justice) of abusing quarantine regulations for the purpose of preventing commercial intercourse, and also for the sake of the profit to be made by farming out the quarantine dues.

The heads of the English law respecting quarantine are contained in the 6 Geo. IV. c. 78. This Act also confers upon the king in council extensive powers for making quarantine regulations. A full official abstract of the regulations established by this statute, and of the orders in council made under it, may be seen in M'Culloch's 'Commercial Dictionary,' article 'Quarantine.'

In 1850, upon the invitation of the French Republican Government, it was agreed among the different states which had coast possessions in, or close to, the Mediterranean, that an international conference on the subject of quarantine should be held in Paris. Delegates attended this meeting from France, Great Britain, Austria, Russia, Sardinia, Tuscany, the Papal States, Naples, Turkey, Greece, Spain, and Portugal. M. David, of France, was appointed president, and the congress sat from the 23rd of July, 1851, to the 19th of January, 1852. Although the resolutions come to by this body are important, they have only been very partially acted on up to this moment by the nations represented. At one of the earliest sittings of the congress it was decided that only two kinds or degrees of quarantine be henceforth recognised; namely, "quarantine of observation," and "quarantine of rigor or strictness," and that the third, or intermediate kind, "suspected quarantine" should be discontinued. Quarantine of observation involves only the enforced detention and isolation of a vessel with all persons and things on board for a specified time, due attention to ventilation and cleanliness being required to be observed. In strict quarantine, besides a longer detention, and a more rigorous isolation, other special precautionary measures, including the disembarkation of persons and the cargo in a lazaretto, and their presumed disinfection by fumigation, &c., are imposed.

At the same congress, it was resolved that the three diseases—plague, yellow-fever, and malignant cholera, should be held in an especial manner as demanding the use of quarantine measures for the protection of a country against their introduction from abroad.

The resolution with regard to cholera was not adopted without much opposition. Dr. Milroy, in his paper on the subject of the convention, reprinted in the transactions of the 'National Association for the Promotion of Social Science' for 1859, says, "The convention based upon, and embodying the results of their deliberations, has hitherto been adopted by only a few of the represented powers, namely, by France and Sardinia in the first instance, and at a later period by Portugal, Tuscany, and Turkey. This country, among others, has most wisely, I think, declined to follow the example; for there is certainly much in the proposed restrictions upon freedom of intercourse, on account of the apprehended risk of imported disease, that appears to me to be unnecessary, and therefore objectionable. And it is a fact not undeserving of notice, that in more than one of the countries which took part in the conference, the quarantine system pursued since 1851 seems to be now actually more vexatious and oppressive than it was before."

The National Association for the Promotion of Social Science appointed a quarantine committee in 1858, who issued a series of queries for transmission to governors of colonies and British consuls in foreign countries, on the subject of quarantine. Replies to these queries have been received from above two hundred different channels, and abstracts of these returns have been published by the Board of Trade. The first abstract, published May, 1860, consists of an "Abstract of the regulations in force in foreign countries respecting quarantine." The second paper consists of "Returns of information on the laws of quarantine," published August, 1860. These papers contain by far the largest amount of information to be obtained at present on the subject, and it is hoped that their publication will lead to permanent changes in the present laws of quarantine.

QUARE IMPEDIT. When an ecclesiastical benefice becomes vacant, unless the patron [ADVOWSON] present his clerk, that is, a clergyman, to the bishop of the diocese for institution, within six calendar months, the right lapses to the bishop, who may collate to the vacant benefice. But if a presentation be made by the patron within the six months, and that presentation is rendered ineffectual by the bishop's refusal to institute the clerk presented, the patron may obtain redress for this interference with his right of patronage in an action of Quare impedit, a proceeding so called because therein the defendant is required to state Quare impedit (why he hinders) the plaintiff from exercising his right of presentation. If the bishop be the sole disturber of the right, as is the case when he rejects the clerk upon an unfounded allegation of personal incapacity, as illiterature, immorality, &c., the action of Quare impedit is brought against the bishop alone. Where the bishop has instituted a clerk upon the presentation of a party wrongfully claiming to be patron, the action is usually brought against the bishop, the patron so claiming, and his clerk jointly; for unless the bishop be made a party to the suit, a title to present by lapse will accrue to him if the suit remain undetermined at the end of the six months, and the clerk instituted is shown to be an intruder. If the clerk be omitted, there can be no process (in a suit to which he is no party) to remove him from the benefice in case he has been instituted; and the consequence will be that the plaintiff must lose his right of presenting for the present turn.

The writ by which this action is now commenced is the same as in other suits (23 & 24 Vict. c. 126, s. 26). The plaintiff, in his declaration, sets out some former presentation to the same benefice, and if that presentation was not by himself, he must formally deduce a title to himself, by descent or purchase, from the party by whom the presentation on some former vacancy is alleged to have been made. The declaration must also show a disturbance before the bringing of the action. Upon this the bishop and the clerk may disclaim all title, save only, the one, as ordinary, to admit and institute, and the other, as presentee of the patron, who is left to defend his own right. But if the bishop has done more than he was bound to do as ordinary, especially where he has wrongfully collated the benefice, the plaintiff may, in his replication, allege special disturbance in the bishop for the purpose of making him a substantial defendant. If the right be found for the plaintiff on the trial, the jury who try the cause are to inquire of three other points: 1st, Whether the church, &c., is full, and if full, of whose presentation; for if it be of the defendant's presentation, then the clerk is removeable, provided the writ has been brought in due time; 2nd, What the value of the living is, and this with a view to the assessment of damages, which are directed to be given by the statute (13 Ed. I.); 3rd, In case of plenarty (that is, of the benefice being full), upon a usurpation, whether six calendar months have passed between the avoidance and the time of bringing the action; because the statute which permits a usurpation to be divested by a Quare impedit, does so only when the action is brought within the six months, and at common law plenarty is a bar to the action of Quare impedit, however early the action may have been commenced. If the jury find that the plaintiff had the right to present, and that his action was commenced within the six months, he has judgment to recover this presentation; and if the church, &c., be full by institution of any clerk, process issues to remove him, unless whilst the action was depending, the bishop (not having been made a party to the suit) has collated by lapse; in which case the plaintiff loses the present presentation, but is entitled to recover the full amount of the income of the benefice for two years from the defendant, the pseudo-patron, as a satisfaction for the turn lost by his disturbance; and in case of inability to pay, the defendant is liable to imprisonment for two years. But if at the termination of the suit the church still remains void, the party to whom the presentation is found to belong, whether plaintiff or defendant, may sue out a writ "ad admittendum clericum," by which the bishop is commanded to admit and institute the clerk of the successful party. If, upon this writ, the clerk be not admitted, the patron may recover satisfaction in damages against the bishop in an action for such refusal.

The patron only, and not the clerk, can maintain an action against the disturber. But under several statutes passed in the reigns of James I., William and Mary, and Anne, which took away the right of presentation from Roman Catholic patrons, the clerks presented are empowered to take certain proceedings in support of their interests. The right of presenting to benefices belonging to Roman Catholic patrons is vested by those statutes in the universities of Oxford and Cambridge, according to a distribution of counties given in the act of James I.; most of the counties in the south and west of England being for this purpose annexed to Oxford, and those in the north and east to Cambridge. The 12 Anne, st. ii. c. 14, provides (s. 4) that besides the writs of Quare impedit which the universities as patrons are entitled to bring, they or their clerks may file a bill in equity against any person presenting to such livings and disturbing their right of patronage, in order to compel a discovery of any secret trusts for the benefit of Roman Catholics in evasion of these statutes: and also (by 11 Geo. II. c. 17) to compel a discovery whether grants or conveyances of such advowsons were made *bonâ fide* to a Protestant purchaser for the benefit of Protestants and for a full consideration; without which requisites every such grant and conveyance of any advowson is declared to be void. This is the only case in which the clerk is at liberty to interfere with the recovery of a presentation of which he is afterwards to have the advantage.

The statutes giving to the universities the right to present to benefices belonging to Roman Catholic patrons do not affect the exercise of the right of patronage in any other class. Dissenters, and even Jews and pagans, may exercise this right. When the disability was first created, persons professing the Roman Catholic religion were the only class from whom any danger in a political or religious point of view was apprehended; and the circumstance that persons who have been admitted to holy orders in the Church of Rome are capable of holding benefices in the Church of England may perhaps have increased the jealousy with which Roman Catholic patrons were regarded by the legislature.

It has lately been held that these statutes do not transfer any right of presentation to the universities where the patronage of a vacant benefice is vested in several parties, unless all of them be persons professing the Roman Catholic religion. If there be two patrons, one a Protestant and the other a Roman Catholic, the entire right of presentation vests in the former.

Finally, no person shall bring a Quare impedit or any suit to enforce a right to present to or bestow any ecclesiastical benefice after the expiration of the period during which three clerks in succession shall have held the same, all of whom shall have obtained possession thereof adversely to the right of such person, or of some person through whom he claims, if the times of such incumbencies taken together shall amount to the full period of sixty years; and if the time of such incumbencies shall not together amount to the full period of sixty years, then after the expiration of such further time as with the times of such incumbencies will make up the full period of sixty years. (3 & 4 Will. IV. c. 27, s. 30.)

QUARRY and QUARRYING. A quarry is an excavation in the ground, from whence are extracted marble, stone, or chalk, for the purposes chiefly of sculpture, building, and civil engineering. The name appears to have been applied to such excavations from the circumstance that the materials obtained from them are there quadrated or formed into rectangular blocks.

Egypt abounds with rocks of calcareous stone, sandstone, and granite; and all these materials have been employed in the formation of the massive works which yet remain to attest the magnificence of the ancient people of that country. The walls of most of the temples were constructed of sandstone, which appears to have been chiefly obtained from the quarries stretching along the banks of the Nile, in the mountains of Silsileh; but the obelisks and statues which adorned those temples are formed of Syenite, or Oriental granite, drawn from the quarries in the islands of Philœ and Elephantine, and particularly from the vast excavations in the mountain terraces about Syene. ('Egypt. Antiq.' 'Library of Entertaining Knowledge.') The stone which has served for the pyramid of Cheops is a carbonate of lime, of a light gray colour; and the same kind of stone forms the interior mass of the pyramid of Mycerinus; but the latter is covered with red granite. The monolith at Sais, in the Delta, was formed of a single block of granite, which was floated down the Nile on a raft, from the quarry in Elephantine. (Herod. ii. 175.)

The master-pieces of Grecian sculpture were executed in the rich white marbles of Attica and the islands of the Archipelago. The quarries of Mount Pentelicus near Athens supplied the materials for the Parthenon and the temple of Theseus in that city, and for the temple of Ceres and Proserpine at Eleusis; and both in Greece and Asia Minor an abundance of stone of a greenish-white was dug from the earth for the ordinary purposes of architecture. The marble of Pentelicus, which lies on the surface of the rocky mountain, was obtained by cutting the side of the hill into vertical cliffs; and about the foot of the escarpment there still remain some of the blocks of marble partly cut in form for the shafts of columns. The quarries at Ephesus are said to have constituted an immense labyrinth. The quarry in the hill Epipolæ, with the stone from which the edifices of Syracuse were constructed, appears to have been of vast extent, since it was capacious enough to contain the 7000 Greek soldiers who had been taken prisoners when the army of Nicias retreated from that city. (Thucyd. vii. 86.) The quarries of the Greeks and Romans were worked by slaves; and as the labour was of a severe kind, we find frequent allusions to the practice of sending unruly slaves to work in the quarries as a punishment.

We learn from Vitruvius (lib. ii. cap. 7) that the buildings of ancient Italy were constructed with stones of several different kinds. The Tiburtine or Travertine stone is a calcareous rock; it was employed in constructing most of the buildings of ancient Rome. The quarries in Umbria and Picenum furnished a white stone which could be cut with a saw, and would stand well in situations where it was sheltered from the weather, but was liable to be destroyed by rain or frost. On the other hand, the red stone obtained from the quarries about the Vulsinian Lake (*Bolsena*), on the borders of Tarquinii, would stand both frost and fire, and would last for ages: on which account it was generally employed for sculptured works. After the destruction of Rome by fire, in the time of Nero, the houses are said to have been rebuilt of the Alban and Gabian stone, which has the property of resisting the action of that element. The quarries of Carrara, on the north-western slope of the Apennines, have long been celebrated for the fine white marble which is so much employed in the north of Europe for statuary.

The British Isles abound with stone of nearly every different kind that can be employed with advantage in architecture. The quarries of Aberdeenshire supply large quantities of the best granite, which is employed for bridges, river walls, and every work where strength and durability are most required. The Peterhead granite from the same county takes a beautiful polish, and is frequently employed for columns, chimney-pieces, and other ornamental works. The Grampian Hills in Scotland, the quarries in the county of Dublin, and those of Newry in the county of Down, in Ireland, also produce several varieties of the like material. In England granite is obtained chiefly, and in great abundance, from the quarries in Cornwall, where that material is usually designated moor-stone.

Sandstone, both red and white, is obtained in large quantities for the purposes of building, from Yorkshire, Lancashire, and Derbyshire; and the principal edifices in Shrewsbury have been constructed chiefly of the white kind which is furnished by the quarries near Grinshill in Shropshire. A millstone-grit, now much used in England, is supplied from Bramley and Hedon in Yorkshire. The red sandstone is dug from the quarries at Barra, Tranent, and other places in Lothian; from those at Kingudie in Perthshire, and also from Arbroath in Forfarshire. In Ireland it is obtained from the quarries in Tipperary, and the county of Cork.

Slate Quarries are noticed in a separate article.

The stone most extensively diffused over England and Ireland is that which is denominated limestone, and which, from the facility it affords for working it, is most generally called freestone. It is quarried to some extent in Gloucestershire, Shropshire, Derbyshire, and Oxfordshire, and a gray species is obtained in Yorkshire and Northamptonshire; but the principal quarries of this material are in Dorsetshire and in the country about Bath. Those in Dorsetshire are situated about Kingston in the Isle of Portland, and at Swanwich, or Swanage, in the Isle of Purbeck. The most extensive quarries about Bath are at Combe Down, where the ground has been undermined for several miles. More than 30,000 tons of Portland stone are said to be exported annually to London, where it has been very generally employed from the time that Inigo Jones used it in the construction of the Banqueting-house at Whitehall. It was also extensively used by Sir Christopher Wren in the building of St. Paul's cathedral, the Monument, and most of the public edifices in the city after the great fire which occurred in 1666. It is, however, not so much used at present as formerly. The stone obtained from Purbeck is of various kinds; some of it, which is capable of taking a good polish, has been used for the pillars of Salisbury and Canterbury cathedrals. It is of a darker colour than Portland stone, and in general it is not so good; the blocks raised from the quarries are also smaller. The material is frequently used as a flag-stone for the steps of buildings and for paving the streets. The hills containing the stone lie in a direction nearly east and west; the beds have a considerable dip or inclination to the horizon, and being covered by a large mass of earth, the men work in quarries under ground. The stone of Portland and Purbeck constitutes the upper oolite formation of the geologists; and in the former district the quarries are cut through several different beds. The first, or that immediately below the vegetable earth, consists of a cream-coloured limestone, three or four feet deep; and next to it is the *cap-stone*, which is of the same colour, very hard, and about ten feet thick. Below these is a species of rock composed of fragments of oystershells cemented together; and still lower is a bed, five feet thick, of good white stone. This is followed by a quantity of flint about six feet deep, a second bed of good stone five feet deep, and a thin layer of stones of small value. The best building-stone lies still deeper, and the beds of it vary in thickness from seven to fourteen feet. Underneath all these are masses of flints, extending to the depth of fifty or sixty feet.

The quarries near Bath furnish the stone which bears the name of that town, and which occurs generally in three beds, of variable thicknesses and different qualities. That in the middle is far superior to those which are above and below it. The depth of the middle bed is in some places as much as 30 feet; the stone when first taken from the quarry is soft, but it becomes hard after having been for a time exposed to the air. The depth of the upper bed varies from 20 to above 50 feet, and the material is either shelly or argillaceous; that of the former kind appears to have been employed by the Romans for the edifices they constructed in this part of the country, and is very durable.

The marble and limestone quarries which were opened near Plymouth in 1812 furnished the material used in the formation of the breakwater at that place; the stone was raised from thence in blocks weighing from one to above five tons. The material selected for the construction of the Houses of Parliament is a magnesian limestone, which abounds in all the tract of country from Durham to Northampton; and that which is actually employed is obtained from several different quarries, principally those near Norfall and Anston in Yorkshire, and near Bolsover in Derbyshire. The unfortunate result of this selection will be found noticed under Stone for Building.

Limestone is found in Scotland, where it is occasionally employed for architectural purposes. It is also plentiful in many parts of Ireland; and quarries of this material, of a rich kind, have been opened in Queen's county, and in the counties of Dublin, Meath, and Cork. The limestone district of Kilkenny is famous for its quarries of black marble so much used for ornamental purposes; and good flagstones for paving are obtained at Shawhill in the same county.

The quarries in the Cotswold Hills in Gloucestershire afford in abundance a blue claystone for building; and the best stones for pavements are obtained from those at Ealand, or Eland, near Halifax in Yorkshire. The quarries near Maidstone, on the south bank of the Medway, produce much of what is called ragstone, a material which is occasionally used in Kent for building, but chiefly in the construction of sea-walls and for paving the roads. Lastly, about Reigate and Godstone in Surrey is found a soft stone which has the property of withstanding the action of fire, and which on that account is much used for chimneys, ovens, and furnaces; but it is scarcely fit for any other purpose.

A valuable table of the principal quarries of sandstone and limestone in England accompanies the 'Report concerning the Qualities of Stone with reference to the New Houses of Parliament' (1839).

Having thus explained the nature of *quarries*, we proceed to notice *quarrying*, which is the operation of extracting from the ground, or detaching from the sides of rocks, marble, stone, or other minerals, in considerable masses; generally also this operation is accompanied by a reduction of the masses to rectangular forms.

When the material to be excavated lies vertically below the surface of the ground, the work commences by removing the earth to a depth sufficient to lay that material bare, in order that it may be separated into blocks, and removed; but when the stone, &c., is in the interior, and near the side of a mountain or hill, the workmen proceed as in the operation of mining, running galleries into the ground, and leaving pillars of the material for the support of the mass above them.

A quarry of small extent is opened by sinking vertically in the ground a shaft, into which the men descend by ladders; and the blocks of stone, being separated from the mass, are drawn up by means of cranes, which are worked by a windlass or other machine. In working the larger quarries, the vegetable mould forming the upper surface is removed by the spade; and the beds immediately underneath, generally consisting of rag, or stone of an inferior quality, are broken up by gunpowder or otherwise, and conveyed to a distance. The stones intended for sale, and which are generally in beds much below the surface, are sometimes also detached from the mass by blasting [Mining]; but as by this process the blocks are broken irregularly and the stone wasted, a different method is generally employed. The large mass of stone, as it exists in the quarry, consists of strata contiguous one to another, and the surfaces in contact form planes of *cleavage*; in lines parallel to which the stones being more easily divided than in any other direction, these lines constitute what is called the *cleaving* grain of the material. In order, therefore, to separate a large block from the mass, a series of iron wedges, placed in line a few inches asunder, on the natural face of the rock and in the direction of the cleaving grain, are driven into the stone till a part is loosened: a channel is then cut in the direction of the length of the intended block, and at a distance from the natural edge of the stone equal to its required breadth; and wedges being planted in the channel, they are driven by repeated strokes till the stone is split in that direction also. In the hardest stones, the wedges are placed not in the channels, but in what are called *pool* holes sunk in the direction in which the block is to be severed from the mass. A similar operation is then performed in the direction of the breadth of the block; and thus a large portion is detached from the original mass.

The natural strata of the stone in different quarries are in different positions; frequently they are horizontal, but generally they are inclined to that plane, and sometimes they are vertical: occasionally also both the first and last of these positions are assumed by the stone in the same quarry. It is evident that the separation of the blocks from a mass must be most easily effected when the natural strata are in vertical positions.

After the blocks have been severed from the mass, they are reduced as nearly as possible to a rectangular form; and this is done by means of a tool called a *kevel*, pointed at one end and flat at the other, with which the irregular parts are knocked off. The blocks are then usually, by means of cranes which are capable of being moved from place to place, raised upon trucks or low carriages; and these are drawn, generally on iron railways, to the quays or wharfs where the stone is put on ship-board. A curious account is given by Vitruvius of an unsuccessful attempt which was made by an engineer named Paconius to bring from a quarry a mass of stone containing about 576 cubic feet. For this purpose, two broad cylinders of wood, 15 feet in diameter, were constructed; and the stone, being raised from the ground, was made to rest between them, the line of its length being in a horizontal position in the direction of their common axis, then a rope being wound round the circumference of the united cylinders in the middle of the length of the latter, and one end of it being made fast to the harness of the oxen, it was intended that, by the motion of the animals, the cylinder should revolve on the ground, and the stone be brought up to its place. The contrivance appears to have failed; but had the oxen been attached to the two ends of the cylinder instead of its middle, there is no reason to doubt that it would have succeeded.

So far as concerns our own country, granite is the hardest stone quarried in any considerable quantity. The largest operation in Cornish granite is believed to have been the detaching and working of a block weighing 33 tons, for an obelisk. The granite of Brown Willy, sent down to Wadebridge for shipment; that of the Cheesewring, shipped at Liskeard; that of the Par Valley, shipped at Par Harbour; and that of Penrhyn, shipped at Falmouth,—are well-known examples of Cornish granite. In some of these quarries the stone is of beautiful texture, and glistens brightly in the sun; so hard is the stone, that the blows of the picks against it give forth a real musical sound, varying in pitch according to the size of the pick. We have said that the use of gunpowder is rather limited in quarries of stone for building, because the substance is apt to be too much shattered by this explosive force. We may, however, refer to Blasting for further information as to this process—especially in those instances where an electric current is employed to ignite the powder. Enormous masses of Holyhead mountain are now being quarried in this way, to furnish materials for a new breakwater in the harbour of refuge; a railway extends from the place of detachment to the place of deposition, thereby greatly facilitating the operations.

At the Aberdeen meeting of the British Association, in 1859, Mr. Gibb gave an account of the Aberdeenshire granite quarries, from which it appears that those quarries have been worked about two centuries and a half. The operations were on a small scale until about the year 1741, when an extensive fire at Aberdeen led to a municipal order that the fronts of houses should be built of stone, instead of wood as heretofore. Aberdeen granite was first used in the London streets in 1764; but Waterloo Bridge was the first great metropolitan work constructed in this stone. The quarries are about twenty in number, and present five kinds of granite, technically known as blue, red or Peterhead, light red, soft gray, and white. It exhibits irregular masses, and a columnar structure. A good deal of blasting is necessary in the operations. The best stone is now found at some depth beneath the surface. Dressing machines have occasionally been tried to bring the blocks of granite into form, but they have not been satisfactory, because they acted like a plane; whereas granite requires a kind of percussive action to bring down the surface. There are about 500 workmen and 50 horses at the quarries. The produce is now about 50,000 tons annually, of which 30,000 tons are exported.

It is right to observe that builders generally consider it advantageous to dispose the stones in the lower part of an edifice in the same position as they had when lying in the quarry; it being understood that they are then best capable of supporting the weight of the superstructure.

QUART, the same word as quarter, but always used (in our language) for the quarter of a gallon. [Gallon.]

QUARTER, the fourth part of anything. The frequency of division into four parts has caused the word to be used sometimes in the sense of a part or portion allotted. Thus the portion of a camp or barrack allotted to one soldier is called his *quarters*.

QUARTER. [Heraldry.]

QUARTER-SESSIONS. [Sessions.]

QUARTER-SQUARES. A table of the fourth part of the squares of numbers may be substituted for one of logarithms in multiplication. For since

$$\frac{(a+b)^2}{4} - \frac{(a-b)^2}{4} = ab,$$

a table which gives the squares of the halves of numbers will, by the addition of the squares of the halves or quarter-squares, give the product. Where $a+b$ and $a-b$ are odd, the fraction ¼ is omitted from both squares, which obviously produces no effect. Thus the *tabular* quarter square of 5 is not 6¼, but 6. [Table.]

QUARTILE, a term of astrology and ancient astronomy. Two bodies are said to have a quartile aspect when their longitudes differ by 90 degrees, or one quarter of the whole great circle.

QUARTZ. [Silicon.]

QUASSIA. The wood of two different trees is known in commerce by this name: one, formerly very common, but now extremely rare, is obtained from the *Quassia amara* (Linn., f. supp. 235, and Woodv., t. 77), a native of Surinam, Guayana, &c.; the other, *Picræna excelsa*, Lindley (*Quassia excelsa*, Swartz), is a native of Jamaica. Both kinds are imported in billets, sometimes a foot in diameter and several feet long; but before being used for medicinal purposes, they are cut into chips, which are of a light gray colour, or, by long exposure to the air, of a yellow or brownish hue. The physical characters of the two sorts are so similar, that it is difficult to distinguish them; but a watery infusion of the Surinam quassia by permuriate of iron is only rendered turbid, with grayish flocculent pieces floating in it, while that of the Jamaica quassia is rendered black by the same re-agent. Both are devoid of odour, but possess an intensely bitter taste, which is stronger but more disagreeable in the Jamaica quassia. This property at once distinguishes quassia from any other wood which may be substituted for it. The active principle seems to be *quassite*, a neutral body, which crystallises in white prisms, and is readily soluble in alcohol. Quassia has a poisonous influence over many of the lower animals, and perhaps even over very susceptible individuals of a higher grade. The infusion of quassia should be made with cold water. The *bitter cup*, now popular, is made of quassia, and is a convenient form of obtaining an infusion.

Quassia is regarded as a pure and simple bitter, possessing tonic properties of a very marked kind; and hence it is useful in many forms of debility, particularly of the stomach and muscular system. It is generally given in the form of infusion, which serves as a convenient vehicle for some of the preparations of iron, especially the protosulphate and the phosphate. The Jamaica quassia ought not to be employed as a vehicle for the permuriate of iron, as an inky fluid, instead of a clear transparent one, is the result. The want of aroma may be obviated by adding to the infusion a portion of the compound tincture of quassia ('Pharm. Edin.'), which renders it more grateful and more beneficial.

Infusion of quassia, sweetened with sugar, is useful to destroy flies, and is much safer than the fly-waters made of king's yellow or orpiment, a poisonous compound of arsenic; for should children or others drink the infusion, improved appetite would be the only result, whereas death is the frequent consequence of drinking the arsenical fly-water.

QUASSIN, or *Quassite* ($C_{20}H_{12}O_6$?). The bitter principle of quassia wood. [Quassia amara, in Nat. Hist. Div.] It may be obtained by treating the solid aqueous extract with alcohol, evaporating, and recrystallising. It forms small, white, opaque prisms, inodorous and very bitter. Nitric acid converts it into oxalic acid.

QUEEN, from the Saxon cþen, used to denote *mulier*, *femina*, *conjux*, as well as the most distinguished of women and wives, to whom now it is only appropriated. The other use of it, as betokening a sovereign princess who has succeeded to the kingly power, is an application of it not originally contemplated.

The king's consort has been regarded in all countries as a person of eminent dignity, and has been invested with privileges not allowed to any other married woman. In England she can purchase lands, and take grants from the king her husband; she has separate courts and officers, including an attorney- and a solicitor-general; she may sue and be sued apart from her husband, have separate goods, and dispose of them by will. She pays no toll, is not subject to amercement, and has a share in fines made to the king for certain privileges, which last is called queen's gold. Anciently manors belonging to the crown were assigned to her in dower, but this provision is now made by a Parliamentary grant. Again, there is thrown over her person a peculiar protection. It is as much treason to compass or imagine the death of the king's consort as of the king himself. To violate or defile her person is also treason, though she be consenting. It has been the usual practice to crown the queen with the same kind of solemnities as at the coronation of a king. In the case of Caroline, the consort of King George IV., who was living at the time apart from her husband, this was not done; but her right was asserted at the time by Mr. Brougham before the Privy Council.

The chief distinction between a queen-dowager and the widow of any other person of eminent rank lies in this, that though she marry with a commoner, she does not lose her rank; but no one can marry a queen-dowager without the special licence of the sovereign.

A queen-regnant, or princess who has inherited the sovereign power, differs in no respect from a king as to the political rights vested in the dignity.

QUEEN-CONSORT. [Queen.]

QUEEN'S METAL is a white alloy, used for making spoons, knife-handles, teapots, &c. It is intermediate in properties between Pewter and Britannia-Metal, and consists of 9 parts of tin, 1 of antimony, 1 of bismuth, and 1 of lead.

QUERCETIC ACID. [Quercitrin.]

QUERCETIN. [Quercitrin.]

QUERCIN. A crystalline matter said to be contained in oak-bark.

QUERCITANNIC ACID. [Tannic Acids.]

QUERCITE ($C_{12}H_{12}O_{12}$). A variety of sugar contained in acorns. It separates out in transparent prismatic crystals from a concentrated and fermented infusion of acorns; the tannin having first been separated by the addition of lime. It is soluble in water and in proof spirit, is not fermentescible, and does not reduce alkaline tartrate of copper. [Mannite.]

QUERCITRIC ACID. [Quercitrin.]

QUERCITRIN. *Quercitric Acid* ($C_{36}H_{18}O_{20}+2$ Aq.). The yellow colouring matter contained in quercitron bark. [Quercus, *tinctoria*, in Nat. Hist. Div.] An alcoholic tincture of the coarsely comminuted bark is treated with gelatin to remove tannic acid; on evaporation quercitrin crystallises out. It is an inodorous, bitter, crystalline powder, slightly soluble in boiling water, absolute alcohol, or ether, readily so in hot acetic acid, and very soluble in solutions of soda or ammonia.

Quercitrin is a glucoside; that is, by the action of dilute acids it breaks up into grape sugar (glucose), and a new body to which the name *quercetin* has been given.

Quercetin ($C_{24}H_{8}O_{10}$) is a citron-yellow granular powder, inodorous and tasteless. It is insoluble in cold water, only slightly soluble in hot water, but very soluble in alcohol or in alkaline solutions. Like quercitrin it is coloured green by perchloride of iron. Hlasiwetz has recently found that quercetin itself contains the elements of a sugar identical with phloroglucin, associated with a crystalline acid to which he gives the name *quercetic acid* ($C_{34}H_{12}O_{8} + 7HO$).

QUERCITRON. The barks of *Quercus tinctoria*, the quercitron or black oak, and of the *Q. alba*, or white oak, of North America, are officinal in the United States, and that of the *Q. tinctoria* in the German pharmacopœia, but not the British. In the former they are employed from convenience, as being indigenous, though confessedly inferior in tannin and astringency to the *Q. Robur* (*pedunculata*) of Europe. The German pharmacopœias give quercitron a place because it furnishes a useful reagent for the salts of iron; its infusion yields no precipitate with gelatine. But its employment in dyeing, and also in dressing leather, is the chief cause of its being imported into Europe. There is one inconvenience in using leather tanned with it, namely, it imparts a yellow colour to the stockings of the wearer. This can be avoided by subjecting the leather to a particular but expensive process.

The same remedial powers, though in less degree, are possessed by quercitron bark as by that of the common oak-bark. It enjoys, justly or unjustly, the same reputation in America, as a preventive or cure of consumption; so persons threatened with consumption resort to bark-mills and tan-works. For medical purposes an infusion with *cold* water is best.

QUERCUS PEDUNCULATA (Willd.) The bark of this species, the true British oak, is used in medicine. Its appearance varies with the age of the bark, as well as of the tree from which it is obtained. Its excellence is determined by the period of the year when the tree has been barked. The best is obtained from coppice oaks, not from old or full-grown trees, and is better from the branches than the trunk. According to Sir H. Davy, the greatest quantity of tannin exists in the bark in spring, at the time when the buds begin to open ('Agricul. Chemistry,' 4th ed., p. 87), which is confirmed by Biggins. This is the period usually selected to decorticate the trees, owing to the greater ease with which it is then effected, the cambium which exists between the bark and wood allowing of their easier separation. The interior cortical layers are much richer in the active principles than the external ones.

Oak-bark is commonly met with in pieces from one to two feet long. That from young stems or branches is generally thin, tolerably smooth, having a silvery or ash-gray cuticle, and frequently clothed with lichens, chiefly of the genus *Verrucaria* or *Opegrapha*. When newly detached it is whitish internally, but by exposure to the air it deepens into brown, and becomes fibrous and cracked. The bark of old stems is much thicker, very rough and cracked, and greatly inferior in quality. The chief chemical constituents are: tannin (impure tannic acid), tannates of lime, magnesia, potash, &c., gallic acid, uncrystallisable sugar, pectin, and lignin. It has the peculiar and well-known odour of tan, and a bitter astringent, but afterwards sweetish, mucilaginous taste.

Oak-bark possesses all the properties of astringent substances, except the power of decomposing tartar-emetic. [ASTRINGENTS; ANTIMONY.] It is more employed externally than internally as a wash or injection. By long-continued application it can almost tan the living tissue, and either strengthen a weak part of the skin, or convert a secreting into a non-secreting surface, as in cases of prolapsed or inverted uterus. One of the most valuable applications, and at the same time cheapest, to surfaces threatened with gangrene from pressure, as in fevers, or old bedridden persons, is a wash formed by digesting oak-bark in weak distilled vinegar, and, after straining, adding hydrochloride of ammonia. It is not only unnecessary, but injurious, to make a decoction of oak-bark: no tanner would think of boiling his oak-bark before steeping his hides in it.

Powdered oak-bark with chamomile flowers is a cheap and often effectual mode of checking the paroxysms of agues.

(Cullen's *Mat. Med.*; Pereira's *Mat. Med.*)

QUERCUS INFECTORIA. [GALLS.]

QUEVENNE'S IRON. [METALS.]

QUI TAM. In those statutes by which certain acts are prohibited under a penalty, it is usual to encourage the enforcing of the penalty by appointing the whole or some part of it to be paid to the person who shall take the risk and trouble, and incur the odium, of bringing the matter before a court of law. Where the part, commonly a moiety, is given to the king, the informer suing for the penalty proceeds in this form: "A. B., who, as well (*qui tam*) for our lady the queen as for himself, in this behalf prosecutes, complains," &c.

When a *qui tam* or other penal action is commenced, no other person can afterwards sue the defendant in respect of the same offence, whatever the result of the first action may be. It is therefore not unusual for offenders against penal statutes to seek to protect themselves by procuring one of their friends to sue. This, however, will be of no avail against a subsequent informer suing *bonâ fide*, provided the fraud and collusion in getting up the first action can be shown.

QUIA EMPTORES. [FEUDAL SYSTEM.]

QUICK HEDGES. [HEDGES.]

QUICKLIME. [CALCIUM.]

QUICKSANDS are those masses of loose or moving sand which are formed on many sea-coasts and generally at the mouths of rivers: those of the Nile and Senegal are among the most remarkable for these accumulations. The sands are generally conveyed by the rivers from the interior of the country, and being at first arrested by the waters of the ocean, they become, in many instances, by the action of the winds and tides, moveable *bars*, which are very dangerous to shipping. The loose sands on the coasts are, when dry, driven by winds over the land, which they then cover often to a considerable depth, overlaying the fertile ground and occasionally entombing whole villages: the coasts of Cornwall and Norfolk in England, and of Jutland in Denmark, are particularly subject to these encroachments [DUNES]; and it is stated that in the latter country there are vast beds of sand so loose as to be incapable of supporting the weight of a man. In Greenland there is a chain of ice-hills between two promontories of moving sand, which is driven by the winds far out to sea.

The easterly movement which gives the character of quicksands to the arenaceous deposits in and around the mouths of the Nile, takes place at all depths, and is extended to the shore itself. It is caused by the westerly gales and prevailing north-west breezes, which have also produced a range of sand-dunes extending from Cape Boulos at the most northerly point of Lake Boulos, eastward of the Rosetta branch of the river, to the mouth of the Damietta branch. These winds are both the accumulating and moving causes of this "stream of sand-dunes," as it has been termed. As fast as the wind removes the sun-dried sand from the beach, the surf re-accumulates it again, during every gale. The quicksands, therefore, are littoral as well as marine phenomena. There is a constant movement of the sand in the depths, both along the shore, and within the shore (which here merely separates the waters of the sea from those of the Delta), commencing from the Rosetta mouth on the east, and extending to the Damietta mouth on the west. It is also blown along the coast in a succession of dunes by one wind, or in part back again into the sea by another, less prevalent, but more violent wind. The subject is importantly connected with that of one of the most remarkable projected enterprises of the present age, the "canalisation" of the Isthmus of Suez, in order to effect a navigable communication between the Mediterranean and the Red Sea. The subject has been treated by one of our most eminent marine-surveying officers, Capt. Thomas A. B. Spratt, R.N., F.R.S., in 'An Investigation of the Effect of the prevailing Wave influence on the Nile's Deposits, and upon the Littoral of its Delta,' dated Alexandria, July 9, 1858, printed with four lithographs of maps and sections, by the British Admiralty in the following year; and from which copious extracts have been made public in a parliamentary return of 1860. The preceding notice of the Niletic deposits has been derived from the original paper. Capt. Spratt's actual investigation was of the most practical nature, by the observation of the winds and sea-currents, the examination of the coast, that of the sea-bottom by dredging, and the mineralogical and chemical examination of the deposits. The result, broadly, is this, that the Mediterranean entrance to the proposed canal would be perpetually filled up by the moving sands of the Nile drifted by the sea along the coast, and that, in the attempt to construct and maintain it, millions of money would be fruitlessly lost in the depths of the sea.

The sand of Bagshot Heath, which rests on the London clay, is in many places, at a few feet below the surface, saturated with water so as to constitute a perfect quicksand: and, on the borders of Oman, in Arabia, there was discovered by Baron von Wrede a remarkable quicksand, which is said to be more than 60 feet deep.

QUICKSILVER. [MERCURY.]

QUIETISM is the name of the doctrine of certain ascetic Christians, who taught that the chief duty of man was to be wrapped up in the continual contemplation and love of God, so as to become totally independent of outward circumstances and of the influence of the senses, and they contended that when a man arrived at this state of perfection, the soul had no further occasion for prayer and other external devotional practices. Quietism is, in fact, the extreme of asceticism and of contemplative devotion. There have been men so disposed in all ages of Christianity, without forming a sect, and even the Mohammedans and Brahmins have their quietists; but it was a Spanish priest called Michael Molinos, in the 17th century, who first embodied the principles of quietism in his works, which were condemned at Rome, where the author was imprisoned and died in 1696. About the same time Madame Guyon, or Guion, in France, showed herself a great advocate of quietism. She was supported by Fenelon, and opposed by Bossuet. [GUYON and FENELON, in BIOG. DIV.]

QUINA, or QUINIA,—one of the alkaloids of cinchona—*Medical properties of.* The mode of procuring this and other alkaloids from bark, and the mode of forming some of the numerous salts and combinations of these bodies, are already given under CINCHONA, ALKALOIDS OF. Soon after their discovery they were employed in the treatment of disease, and possessed some advantages over the crude bark, the insolubility of the woody fibre of which seriously distressed the stomach. A brief notice of these can only be given here; for fuller details reference may be made to Pereira's 'Mat. Med.;' Royle's 'Mat. Med.;' but the fullest exists in Dierbach, 'Die Neuesten Entdeckungen in der Mat. Med.,' vols. i. and ii. Pure quinia is too insoluble to admit of use. Some of its salts or solutions are used. Cinchonia is more soluble, but it also is only given in solution or combination. These may be classed under the acids, inorganic and organic, and the menstrua or solvents employed to facilitate their administration, augment their power, or render them more grateful to the patient. Of all, the most common is the sulphate of quinia. This is found in two states—the strictly neutral, formerly called disulphate, and the bisulphate. The superior solubility of the former entitles it to preference. Disulphate of cinchonine, and disulphate of quinidina (both termed sulphate of cinchonia, and sulphate of quinidina, though there are also bisulphates of these alkaloids) have the advantage of greater cheapness, and probably equal efficacy. A combination of an inorganic acid and an organic, in the form of a sulpho-tartrate of quinia, in syrup, has been used, but probably it has scarcely any advantage but from its greater palatableness, a merit found in a saccharated solution of bark, or combining extract of bark with confection of orange-peel, which renders it acceptable to children. Similar properties to this last combination are found in the officinal compound tincture of quinia. Amorphous quinine, as it is found in quinoidine, along with several other bases, is a most valuable form, and has the great advantage of comparative cheapness, a circumstance which fits it well for camp and hospital practice, since its efficacy as an anti-periodic is unquestionable. In one of the forms of elephantiasis, which is of a febrile character, and of malarious origin, and markedly periodic in its nature, the utility of quinine is most striking; and as this occurs mostly among the poor, a cheap but effectual remedy is most desirable.

Hydrochlorate or muriate of quina has the advantage of greater solubility than the sulphate, and seems, for this or other reasons, to possess a superior power over some forms of quartan ague, particularly of a typhoid type. Nitrate of quina is very insoluble in water, but easily so in alcohol. A tincture is therefore a good form. Phosphate of quina is equally and easily soluble in water and in alcohol—either may be used as its solvent. In the treatment of the nervous exhaustion of literary men, this preparation is of great utility.

Of the combinations of quina or cinchonia with organic acids the citrate seems entitled to preference. It is of great service. On account of its dearness sulphate of quina is often substituted for it; but when pure its curative properties seem very decided, especially against headaches of malarious origin. It may be taken along with lemon juice. [Orange.] A syrup also is formed, which is acceptable to children. Citrate of quinine and iron is a most eligible combination. Kinate and tannate of quinine are both useful forms. Arsenite and arseniate of quinine are forms of much utility, both in intermittent diseases and in skin affections, particularly if, in the latter cases, associated with sulphur.

Tartrate of quina is little known or used, except as a sulpho-tartrate above mentioned.

Acetate of quina is likewise little known, but an acetate of quinidina alone, which is less nauseous than the sulphate of quinidina, or in conjunction with this last preparation, is a very potent anti-periodic. Acetate of quina and iron is also a commendable tonic, especially in cramp of the stomach.

Valerianate of quina is liable to the objection that it has a most repulsive odour. But its efficacy as a tonic in nervous affections is very great; and in Asiatic cholera it has proved a useful support.

Hydriodate of quina is well suited to the debility of strumous persons.

Hydrocyanate of quina is well suited both for some cases of intermittents, in which the sulphate, from its heating properties, cannot be borne, and for all cases where a tonic and antispasmodic are indicated, such as convulsive disorders, St. Vitus' dance, &c.

Ferro-cyanate of quina is very soluble in alcohol, but not in cold water, while it is entirely decomposed by hot water. It is appropriate to tertian and quartan agues, especially where the sulphate cannot be borne.

Lactate, oxalate, and chloride are fitted for some peculiar cases, and have their respective advocates.

The ammoniated liquor of quina is one of the best preparations, and one of the most speedily acting. In severe influenza and depressed states of the system, it surpasses all other forms; but some persons cannot bear ammonia. Wines of quinine and wines of quinium exist, and are in request, but many owe as much to the wine as the quinine for the favour they enjoy.

Solutions of quinine, of hydriodate of quinine, and of valerianate of quinine in codliver oil are vended, but rapid decomposition occurs. So they should only be prepared immediately before they are to be taken.

QUINCE. The fruit so called is the *Cydonia vulgaris* of botanists, of which there are three varieties, the apple-shaped, pear-shaped, and the Portugal quince. The last is by some reckoned a species. There are also some sub-varieties of the others. The quince-tree is used, and chiefly propagated in this country, for furnishing stocks for grafting with such pears as are intended to be grown as dwarfs, or when early fruiting is desired. The Portugal quince is to be preferred for this purpose, as its growth corresponds nearer with that of the pear than the other smaller-leaved sorts. It is also better for the domestic purposes to which the fruit of the quince is applied, such as marmalade, and syrups or jellies. The propagation of the trees is easily effected by layering, but they root and grow slowly; and seedlings form the best stocks, though they require two or three years longer than these from layers before grafting. As the tree vegetates early, it should, when used as a stock, be grafted as soon as the weather will permit. From this not being attended to, a want of success has occasionally been complained of. The stocks should be headed down even as early as January. Quinces are best adapted for light and rather moist soils. In dry soils the pears grown upon them are rendered gritty. [Cydonia, in Nat. Hist. Div.]

QUINDECAGON, a figure of fifteen sides.

QUINETINE. [Cinchona, Alkaloids of.]

QUINIC ACID. [Kinic Acid.]

QUINIC ETHER. [Ethyl.]

QUINIA. [Cinchona, Alkaloids of.]

QUINICINE. [Cinchona, Alkaloids of.]

QUINIDINE. [Cinchona, Alkaloids of.]

QUININE. [Cinchona, Alkaloids of.]

QUINOIDINE. [Cinchona, Alkaloids of.]

QUINÖIL. Synonymous with Kinoil. [Kinic Acid.]

QUINOLINE. [Cinchona, Alkaloids of.]

QUINONAMIDE ($C_{12}H_5NO_2$), *Kinonamide*. An emerald-green crystalline product, obtained by the action of ammonia upon kinone.

QUINONE. Synonymous with Kinone. [Kinic Acid.]

QUINONIC ACID ($C_{12}H_4O_8$), *Kinonic Acid*. This acid has not yet been obtained in a separate state, but several of its derivatives are known. The following are the names and formulæ of the principal:—

Chloranilic acid	$C_{12}H_2Cl_2O_8$
Chloranilamide	$C_{12}H_4Cl_2N_2O_4$
Chloranilam or chloranilamic acid	$C_{12}H_3Cl_2NO_6$
Chloranilammon or chloranilamate of ammonia	$C_{12}H_2(NH_4)Cl_2NO_6$

QUINONIC GROUP. [Kinonic Group.]

QUINOTANNIC ACID. [Tannic Acids; *Kinotannic Acid.*]

QUINOVATIC ACID. Synonymous with Kinovatic Acid. It is sometimes called chiococcic acid, and esculic acid.

QUINOVIC ACID. Synonymous with Kinovic Acid.

QUINSY, or Cynanche, or Angina, is an inflammation of the throat. Nosologists, having applied the name of cynanche to nearly all the inflammatory diseases in this part, have been obliged to distinguish the different affections of the several organs included in it, by specific names; hence we have *Cynanche parotidæa*, another name for mumps; *C. trachealis*, which is croup; *C. pharyngea*, or inflammation of the pharynx; *C. tonsillaris*, or inflammation of the tonsils; and many other species, named either from the organ chiefly affected, or the character of the inflammation. Of these, mumps and croup having been treated of in separate articles, the present may be devoted to the two last mentioned, which are indeed those that are commonly intended by the popular name quinsy.

Cynanche pharyngea, or inflammation of the mucous membrane lining the back of the mouth and the upper part of the throat, is that which usually exists in a common sore throat, brought on, as it most frequently is, by a change in the weather, or by sitting in cold or damp air. It is usually a mild disease, and chiefly annoying from its liability to recur on slight occasions. The extent of the inflammation varies greatly in different cases; it may be confined to the pharynx, or it may spread from it over the soft palate and the tonsils, and into the cavities of the nose, where it produces the additional symptoms of a cold, or into the tympanum, giving rise to deafness. On examination the back of the mouth and fauces, when thus inflamed, will be found unnaturally red and swollen, and often covered with tough mucus or lymph; and from these changes there result dryness and soreness of the throat, pain on swallowing, and a sensation as if the diseased parts were closely constricted.

A common sore throat does not need much treatment; warmth, gentle purgatives, and sweating medicines, the avoidance of stimulating food, and the inhaling of the vapour of hot water, or hot vinegar and water, or the application of a large poultice round the throat, will usually effect its removal in a few days. Sometimes however the disease is prolonged in a slight but obstinate form, which is commonly called a relaxed sore throat. In this condition the redness of the parts affected is still observed, but it is of a less vivid colour, and is irregularly streaky, instead of being evenly diffused; the velum also, which is commonly implicated, is elongated, and it is from its unnatural contact with the back of the tongue and the epiglottis that the tickling sensation in the throat arises, and excites a constant desire to swallow or to cough. For this condition the necessary treatment consists of stimulating gargles, such as hot wine, infusion of Cayenne pepper, very diluted mineral acids, &c., and if the patient be in general ill health, tonics and appropriate alteratives.

In more severe cases of inflammation of the pharynx and adjacent parts, matter sometimes forms either around or near the pharynx, or in the soft palate of the uvula. Wherever the existence of matter can be determined, it should be immediately let out, as from an abscess in any other part of the body. In other severe, and in some measure peculiar cases, the intensity of the inflammation is marked by the formation of false membranes on the affected surface. This form of the disease has been named *angina membranacea*, and has been especially described by M. Bretonneau and other French physicians under the name of *diphtherite*. [Diphtheria.] In its essential nature this affection resembles croup, with which also it is sometimes connected, the false membrane being not only spread over the mucous surfaces of the pharynx and fauces, but extending down into the trachea. In some cases the inflammation is very acute, and, being accompanied by common inflammatory fever, requires for its reduction the most active antiphlogistic treatment; the same measures, in short, as are applicable in cases of croup. [Croup.] In another severe form of quinsy, the inflammation and formation of false membranes are accompanied by a low typhoid state with great prostration of strength, and requiring all the remedies that are used in cases of low typhus fever, in malignant scarlet fever, and other dangerous diseases of the same class. It is this form of disease which is usually called putrid or malignant sore throat, and by nosologists, *Cynanche* or *Angina maligna*. It sometimes occurs as an epidemic, and was long regarded as attended by sloughing of the throat, the layers of false membrane being mistaken for the inflamed tissue in a state of gangrene. In other cases of this form of cynanche there is a tendency to the production of ulcers. These may be distinguished from diphtheria by the circumscribed character of the inflammation. The accompanying fever is of a more or less low form. The ulcers should be touched with nitrate of silver, and afterwards a most effectual remedy is a lotion of chlorate of potash with hydrochloric acid. In these cases the system requires support, and beef tea, port wine, and quinine should be administered.

In *Cynanche tonsillaris*, or tonsillitis, the inflammation is entirely or nearly limited to the tonsils. Its symptoms are scarcely distinguishable from those of the common form of the preceding disease, but on examining the throat the redness is seen to be less diffused, and the tonsils, being more or less increased in size, are approximated to each other so as nearly to block up the posterior aperture of the mouth, and render any effort to swallow extremely painful. Hence, to avoid the pain, the patient usually lets the saliva flow from his mouth, and often, in attempting to swallow, is unable to overcome the obstacle presented by the enlarged tonsils, and discharges the fluid back through the nose. In many cases also the inflammation extends to the eustachian tube and tympanum, producing deafness, and to the parts immediately around the larynx, giving rise to difficulty of breathing and a harsh hoarse sound of the voice. With these local symptoms there is usually more or less fever, with headache, loss of appetite, &c.

The milder cases of inflammation of the tonsils may be treated in the same manner as those of the preceding disease; leeches applied to the sides of the throat where the pain is most severely felt, are probably the most beneficial means that can be employed. The direct application of powdered alum to the tonsils is very useful. With a higher degree of inflammation abscesses often form in the tonsils, accompanied by all their usual signs, and with still greater obstruction in the throat. In time these will break of themselves, but it will materially shorten the patient's sufferings if they be opened as soon as matter has distinctly collected. The operation should be performed with a guarded knife, or with one that slips through a canula and can have the length of its cutting part fixed.

The most annoying result of repeated inflammation of the tonsils (and those who have once suffered are peculiarly liable to a recurrence of the disease from very slight causes), is, that they become permanently enlarged. In this state, although swallowing is not painful, it is often attended with difficulty, and by the partial closure of the fauces the respiration is always obstructed and requires an effort for its effectual performance. From this, in children, a peculiar deformity of the chest often results, the breast-bone and the fronts of the ribs becoming elevated and very much arched forwards, in a form which is commonly called chicken-breasted. But if this do not occur, the patient always suffers inconvenience from hoarseness and a kind of nasal sound of the voice; he cannot avoid snoring very loud in his sleep, and often starts up from it with a feeling of impending suffocation. The best means for the removal of this state are astringent gargles, as those with alum, oak-bark, mineral acids, &c. Iodine also, administered internally and rubbed on the throat, often proves useful; but in many cases nothing will alleviate the condition of the patient but cutting off a portion of each tonsil, so as to reduce them to their natural dimensions.

QUINTAL generally means the weight of a hundred pounds; but the term is not now English.

QUINTICHLOROPHENIC ACID. A product of the action of chlorine upon trichlorophenic acid [Phenylic Group], or upon chlorisatin [Indigo]. It is crystalline and volatile, and forms crystalline salts with bases.

QUINTILE, a term of astrology and ancient astronomy, meaning distant in longitude by 72 degrees, or the fifth part of the whole great circle.

QUIT RENT. [Rent.]

QUO WARRANTO. A writ in the nature of a writ of right for the crown, which lies against any person or corporation that has usurped or unjustly claims any public office or other franchise or liberty, or that, having originally had a grant of one, has forfeited it by abuse or neglect. Proceedings under it are prosecuted in the Queen's Bench, and the defendant is called on to show *by what warrant* (*quo warranto*) he exercises the office, liberty, or franchise in question. The first process against him is by summons. If he fail to appear in the same term in which he is summoned, he loses his franchise. After appearance, he may disclaim any title, either to the whole or part of the franchise; or he may plead in justification, showing by what warrant he has exercised it. To this plea there may be either a demurrer or replication, and subsequent proceedings as in ordinary actions. On disclaimer judgment is immediately given for the crown. In that case, or on judgment for the crown on demurrer, or after trial, the judgment is that the franchise shall be seised into the hands of the crown, or, if the crown cannot have the franchise, that the defendant shall be ousted, that is, ejected. If the judgment be for the defendant, it is that he may enjoy the franchise, &c., saving the right of the crown, and this saving applies to all titles except that on which judgment is given. The judgment is conclusive even against the crown. (2 'Inst.,' 282; Co., 'Ent.,' 527, &c.)

Proceedings under a writ of quo warranto have, however, been superseded by informations in the nature of a quo warranto, these latter being adapted to attain the same ends, and, at the same time, more expeditious. The judgment is not in this case conclusive against the crown. Except when exhibited by the attorney-general, they are filed by leave of the court.

The statute of the 9 Anne, c. 20, was passed for the purpose of facilitating such proceedings in the case of corporate offices. For although their ostensible object is the punishment by fine, as well as the ejection of the usurper from his office, these proceedings are virtually of a civil nature, and are now almost exclusively employed for the decision of questions relative to the exercise of corporate rights between mere individuals. The prosecutor is styled the relator, and must apply by motion in open court for leave to file an information upon affidavits of all the facts upon which it is grounded. The court may either grant or refuse a rule nisi, and if a rule be granted, the case comes on for argument in the ordinary course. The defendant may then either support his opposition by affidavits stating the facts which form the grounds of it, or confine himself to arguments arising on the case presented by the relator. If the rule be made absolute, the defendant must plead, at latest, within the next term, but if the plea be insufficient, the court will allow the defendant to amend at any time before trial. In other respects, the pleading is conducted on the same principles as in ordinary cases. If the defendant be found guilty, the court may give judgment of ouster as well as fine. By the statute of Anne, costs are given to the relator against the defendant, if the information be successful; to the defendant against the relator, if it wholly fail. If one material issue be found for the crown, the crown must have judgment, and the relator is entitled to costs on all the issues. The provisions of the statute of Anne only relate to offices analogous to those mentioned, that is, those of a corporate character. By the statute 33 Geo. III. c. 58, the defendant is enabled to plead that he had exercised the office in question for six years previous to the exhibition of the information, and if the fact be so, he is entitled to judgment. By stat. 1 Vict. c. 78, s. 23, the time within which proceedings of quo warranto may be brought against any mayor, alderman, councillor, or burgess, is further limited to one year after either his election to office, or the commencement of his disqualification. (Com. *Dig.*, tit. Quo Warranto; Bl. *Com.*)

QUORUM. [Sessions.]

QUOTIENT, or **QUOTE,** the result of dividing one number by another.

R.

R is one of the vibrating letters called liquids. It is formed at the back of the palate, and is on this account more nearly related to the liquid *l* than to *n* or *m*. For the various forms of the alphabetical symbol see Alphabet. It is convertible

1, with *l*. See that letter.
2, with *n*. See that letter.
3, with *rn* at the end of words. See N.
4, with *s*. See S.

5. It is apt to place itself at one time before, at another after a vowel. Thus in Greek *κροκοδειλος* or *κορκοδειλος*, *κρατος* or *καρτος*. So the English words *red*, *run*, are changed in the Dorsetshire dialect to *hird*, *hirn*. Again, *brid* is an old orthography of *bird*, and the town *Bridlington* is pronounced *Burlington*.

6. The letter *r*, in the neighbourhood of several consonants, is apt to disappear from words. Thus the German *sprech-en* is in English *speak*, our word *world* is in German *welt*.

7. In one language a word is found with an initial *r*, when in other allied languages there occur at the beginning two consonants, as *br*, *fr*, *wr*. Thus in Greek we have *ροδον*, *ρηγνυμι*, *ρεζω*, connected with which are the forms *βροδον*, *frango*, Latin, and *break*, English; and, thirdly, the English words *wreak*, *work*, *wrought*.

8. The letter *r* is at times confounded with *w*. Thus it is not a very rare variety of articulation that *rubbish* is pronounced *wubbish*.

9. More particularly when a word ends in a *w*, or even a vowel, it is not uncommon to pronounce an *r*, especially if the next word begins with a vowel. The London vulgarism, *winder*, *piller*, for *window*, *pillow*, is an example, nor need the philologist be ashamed to treat of such cases, which are as worthy of consideration as any dialect of the Greek tongue.

RABBI (*ῥαββί*, רַבִּי), a title of respect, similar in meaning to our word master or teacher, which was given to the teachers of the Jewish law by their disciples and the people in the time of Christ. (Matt., xxiii. 7.) The title was often given to Christ by his disciples. (Matt., xxvi. 25, 49; Mark, ix. 5; xi. 21; John, i. 38; iv. 31.) It is doubtful when it was first introduced. It is admitted by Jewish writers that it was not in use before the time of Hillel of Babylon, who lived in the 1st century before the Christian era; and it was perhaps first introduced into the Jewish schools about the time of Christ. The word was originally used in three forms: *Rab* (רַב), as the lowest degree of honour; *Rabbi* (רַבִּי), of higher dignity; and *Rabbun* (רַבּוּן), or *Rabboni* (*ῥαββονί*), which was the most honourable of all. The title of Rabboni is given to Christ on two occasions in the evangelists. (Mark, x. 51; John, xx. 16.)

The title of rabbi has continued in use among the Jews in modern times. The term rabbinical has been given to all the Jewish writings composed after the Christian era.

(Buxtorf, *Lexic. Chald. Rab. Talmud.*, 2176; Lightfoot, *Hor. Hebr. ad Math.*, xxiii. 7; Hill, *De Hebraeor. Rabbinis*, Jen. 1741; Winer, *Biblisches Realwörterbuch*, art. Rabbi.)

RABDOLOGY. [Napier's Bones.]

RACEMIC ACID. [Tartaric Acid.]

RACHITIS. [Rickets.]

RACK. [Arrack.]

RACK. [Torture.]

RADIATION OF HEAT is a motion of its particles in rectilinear directions, diverging every way from a heated body, either luminous or not; and it is imagined to arise from the existence of a strongly repulsive power by which the particles are made to recede from each other with great velocity.

The intensity of heat thus emitted from a point of radiation is obviously the same at equal distances from the point; and at unequal distances, it is inversely proportional to the squares of the distances. The radiating particles falling upon the surfaces of any bodies in the vicinity of that from which they emanate, are, according to the nature of those bodies, absorbed in them, or transmitted through them, or again they may be reflected from them; and, in the two last cases, the radiant heat, as it is called, appears to suffer modifications analogous to those which, in like circumstances, take place in light. According to M. Prevost ('Essai sur la Calorique Rayonnante,' 1809), the radiation of heat is a process which is perpetually going on among all the bodies in nature; those which are of equal temperature mutually interchanging equal quantities of caloric; but, with respect to two bodies which are unequally heated, that which has the greatest quantity sends forth emanations in greater abundance than the other; the difference however diminishing as both bodies approach to an equality of temperature.

The particles of heat (calorific particles) appear to move with perfect freedom through a vacuum, and to be impeded, but in an insensible degree, in their progress through air or any of the gases; they are also found capable of being transmitted, though in small quantities through transparent media of the denser kinds, as glass, rock-crystal, &c.; and in passing through air they produce no sensible effect on the temperature of the latter. If a body be heated to any degree of temperature, and be placed in an absolute vacuum, it is evident that, in consequence of the repulsive power above mentioned, the heat must at length be entirely dissipated by the radiation merely; and if the body be placed in any fluid, it may be readily concluded that the abstraction of the heat must be influenced by the conducting power of the fluid.

The first direct experiments which appear to have been made on the radiation and reflection of heat are those of Mariotte, and an account of them is given in the 'Mémoires de l'Acad.,' 1682. He caused the heat of a fire to fall on the surface of a concave mirror, and observed that it was concentrated in the focus of the latter; and on placing a plate of glass between the fire and the mirror, he perceived that the rays of heat were intercepted. The subject does not appear to have been much attended to till about the middle of the 18th century, when Lambert, in his 'Photometria' (1760), states that, on placing a large glass lens before a fire, the heat was scarcely sensible at the focus, while the reflected heat of burning charcoal set fire to combustibles at a considerable distance; and Scheele, in his treatise on air and fire, which appears to have been written in 1775, describes radiant heat as differing from ordinary heat by disseminating itself in right lines whose directions are not changed by the agitations of the air, and by being reflected from polished metallic mirrors, while it is absorbed in those of glass, and in the others when their surfaces are blackened.

The experiments of Scheele were varied by MM. Saussure and Pictet, who by an appropriate apparatus endeavoured to ascertain the laws of the radiation of caloric. They employed for this purpose two concave mirrors of polished tin, in the focus of one of which was placed the bulb of a Réaumur's thermometer, and in that of the other a ball of iron heated below the degree necessary to render it luminous; and, by a comparison of the height of the mercury in the thermometer with that in one which was placed out of the focus, but at an equal distance from the iron, the difference was found to be equal to about 8 degrees. M. Pictet employed also, in place of the heated ball, a glass flask containing boiling water, in order to avoid the risk of any light being combined with the heat; and the effect produced on the thermometer sufficiently proved that the calorific rays exist independently of those of light. (Pictet, 'Essai sur le Feu,' 1790.) In pursuance of the experiments of Scheele with a blackened mirror, M. Pictet covered with lampblack the bulb of the thermometer in the focus of one of his mirrors, and found that the concentrated heat from the flask, which when the bulb was bright raised the mercury 2⅛ degrees, now raised it 4⅛ degrees. The same experimenter placed a flask of snow in the focus of one metallic reflector, and a thermometer in that of another; and the observed fall of the mercury was then considered as an indication that cold is susceptible of radiation and reflection like heat. The last experiment belongs however to an earlier date, as may be seen by reference to a letter from Oldenburg, dated 1665, in Boyle's Works (fo. 1744).

The nature of the apparatus, and the experiments made by Leslie on the radiation of heat, are described under Heat. From these it appeared that the amount of radiation from a polished surface was only about one-eighth of that which took place from a surface without polish; and hence it was evident that the velocity of radiation depends more on the surface than on the nature of the radiating body. In making experiments respecting the absorbing power of substances, Leslie found that when the heat from the canister was suffered to fall on the glass bulb of the differential thermometer, the quantity received by the latter, if covered with tin-foil having a polish, was only one-fifth of that which it received in its ordinary state.

Leslie also repeated the experiments of Pictet for determining what was called the radiation of cold; and filling his canister with ice or snow, he found that the cold apparently emitted from the varnished side was the greatest, and that from the polished side the least; he observed also that the cold, like the radiant heat, varied with changes in the absorbent power of the thermometer and of the surface of the mirror. The mercury in the thermometer fell more when the mirror was of polished metal than when of glass; it also fell more when the bulb was in its ordinary state than when covered with a polished tin-foil. ('Inquiry into the Nature of Heat,' 1804.) These circumstances, which seemed at one time to favour the opinion that cold had a material existence like heat, have received an explanation from M. Prevost of Geneva. ('Journal de Physique,' xxxviii.) This philosopher observes that a mass of ice or snow may send out radiant heat less in abundance than that which is emitted from other bodies in its vicinity; and this comparatively small quantity of heat, when reflected from one mirror to the other, and from the surface of the latter to the focus, may there produce the effect of absolute cold, by causing the thermometer to send out radiant heat to the ice, and thus render the mercury in it lower than it would otherwise be. This interchange of caloric between the thermometer and the ice may be conceived to go on, the former on the whole losing, and the latter acquiring it, till an equilibrium is established between their temperatures.

From the results of Leslie's experiments, it is apparent that the power by which bodies absorb heat is directly proportional to that by which they allow it to radiate from them; and that both are inversely so to the power of reflecting it. When the rays of heat fall on polished glass, a large portion of them is absorbed; these raise the temperature of the glass, and from the surface of the latter that heat is afterwards radiated in abundance; whereas, when the rays strike the surface of polished metal, nearly all of them are reflected. It was found however that different metals, independently of their polish, have different degrees of reflecting and radiating power. A mirror of tin being rubbed with mercury, the reflection was increased in the ratio of 12 to 20, though the degree of polish was the same; and a metal having lost some of its brilliancy by oxidation, the radiating power was proportionally augmented.

Leslie's canister was found, moreover, to produce different effects, according to the thickness of the covering material on its sides. One coat of jelly on the tin side produced an elevation of the thermometer equal to 38°, and four such coats produced an effect equal to 54°; but after a certain thickness the difference was insensible. A plate of metallic leaf rendered however the radiating power as great as a thick plate of the same metal.

Experiments made by Count Rumford, soon after the publication of Leslie's work, produced nearly the same results as the latter had obtained; and the Count draws from them several useful conclusions. He observes ('Phil. Trans.', 1804) that when we would confine heated substances, solid or fluid, in a vessel, the surface of the latter should be highly polished; on the other hand, if the object be to cool the substances, the surface should be painted or varnished, or be covered with a soft coating which is not metallic. Also, in warming apartments by steam, the intention being to promote radiation as much as possible, the tubes conveying the steam should be unpolished or painted.

In pursuing the views of Scheele concerning the transmission of heat through screens, Leslie found that a sheet of tin interposed between the canister and the mirror entirely intercepted the heat, and a plate of glass nearly so. Employing two sheets of tin, each of which had one side covered with black varnish, while the other side was polished, the following were the results: when the varnished sides were in contact, little heat passed through, evidently because one of the exterior sides was not well adapted to receive the caloric, nor the other to radiate the little which might have been acquired; but when the varnished sides were placed exteriorly, the quantity which passed through was considerable, the varnish enabling one plate easily to absorb and the other as easily to radiate the heat.

The reality of the transmission of heat through glass plates, which both Leslie and Brewster appeared to doubt, from the difficulty of distinguishing between heat so transmitted and that which radiates from the glass after having been for a time absorbed in it, is now supposed to be sufficiently established by the experiments of MM. Prevost and De la Roche ('Annals of Philos.,' 1803), and also by the researches of M. Melloni. ('Annales de Chimie,' xlviii., &c.) The first, in order to ascertain the fact, received on a thermometer the rays from a heated body after passing through screens of glass which were renewed so often that they had not time to become heated. The second suffered a thermometer to rise to its maximum by the rays from a heated body when a transparent glass screen was interposed; and again, when there was interposed a glass screen blackened so as to prevent the radiant heat from passing, the excess of the rise of the thermometer in the former case above that in the latter gave evidently the effect produced by the radiant heat alone. The conclusion at which the experimenters arrive is, that the quantity of heat which radiates through glass is so much the greater as the temperature of the source of the heat is higher. M. Melloni found that of 100 rays incident on the same plate of glass from an oil-lamp, from red-hot platinum, from copper heated to 734°, and from the same heated to 212°, the numbers were 77, 57, 34, and 12, respectively. He has also ascertained that all bodies which have the power of transmitting heat are in general more or less transparent; and that rock-salt is the only known substance in which all the radiant heat falling on it is either reflected or transmitted, whether the temperature of the heated body be low or high.

Diathermacy does not depend upon transparency, either in solids or in liquids. An iron ball heated to 100°, placed midway between the blackened balls of a thermoscope, will not cause a rise in the liquid, since each bulb receives an equal share of heat; but if a plate of rock-salt be interposed between the iron and one of the bulbs, and a plate of glass of equal thickness between the hot ball and the other bulb, the bulb next the rock-salt will rise in temperature much more rapidly than the one next the glass, although both screens are equal in thickness, and equally transparent to light. So also, if four liquids equally transparent receive each 100 rays from an argand lamp, water will transmit only 11, sulphuric acid 17, ether 21, and oil of turpentine 31; while chloride of sulphur, which is of a reddish colour, allows 63 rays to pass. The diathermacy of different solids and liquids for heat from different sources is stated in a tabulated form in such books as Miller's 'Chemical Physics.' We do not repeat them here; but state a few of the more modern results given in that work in connection with the subject.

Knoblauch has found that very thin metallic films are diathermic, thus presenting an analogy to their limited transparency to light. Gold and silver transmit certain calorific rays more freely than others, while platinum appears to transmit all the rays with equal facility. Tyndall has found that the gases exert different degrees of absorptive action on the rays of heat; thus, coal gas is more absorptive than atmospheric air, and the vapour of ether considerably more than that of the bisulphide of carbon. Certain rays are more powerfully absorbed by the colourless gases than others. Thus coal gas arrests the heat rays from a source below a visible red heat much more perfectly than it absorbs the rays of the lime-light after they have traversed a thin layer of water.

Diathermacy is not dependent on transparency; thus black glass and plates of smoked quartz, so opaque that the midday sun is barely visible through them, are much more diathermanous than plates of alum; and plates of quartz smoked so as to be opaque are more diathermanous than when clean and transparent. Diathermacy seems to be more influenced by mechanical arrangement than by chemical composition. Common table salt is adiathermic: a solution of rock-salt is scarcely superior to pure water in diathermacy, and a solution of alum is equal to one of rock-salt. The latter substance in the solid colourless form approaches perfection in diathermacy as already noticed. But even this has lately been found to absorb certain of the rays of heat somewhat more freely than others. All other bodies examined by Melloni transmit a quantity of heat which varies with the nature of the source, just as coloured media transmit quantities of light depending on the nature of the colour. Thus if a pencil of solar light fall upon red glass, red rays alone will be transmitted, the rest being absorbed. This property, whereby different partially diathermanous media absorb different constituents of the thermic pencil, has been termed *thermo-chrosis* or "calorific tint." For as a pencil of solar light incident first on a red plate, and then on one of bluish green, will be totally absorbed, the second plate absorbing what the first transmitted, so a ray of heat may be entirely absorbed by causing it to pass through two media, one of which absorbs the rays transmitted by the other.

By letting the calorific rays pass first through one screen and then through two, M. De la Roche found that, in passing through the second screen, the rays suffered less diminution of intensity than in passing through the first; and the fact is considered as proving that some calorific rays experience more difficulty in passing through glass than others; consequently that, like light, radiant heat is of different kinds. He also observed that a thick plate of glass allows a smaller quantity of radiant heat to pass through than a thin one, and that the difference is so much the less as the temperature of the heated body is higher: and it is inferred that, since radiant heat becomes more capable of penetrating glass as the temperature increases, till the body becomes luminous, heat is only a modification of light.

The theory of radiant heat is intimately connected with that of the cooling of bodies; and the first effort to determine the laws relating to this subject was made by Sir Isaac Newton, who, from theoretical considerations, inferred that when a heated body is exposed to a constant cooling cause, as the uniform action of a current of air, it ought to lose at each instant a quantity of heat proportional to the excess of its temperature above that of the surrounding air, and consequently that its losses of heat in equal intervals of time should form a decreasing geometrical progression. But it is now known that this law holds good only when the differences of temperature do not exceed 40 or 50 degrees, and its inaccuracy at high temperatures was first pointed out by Martine (1740).

From the experiments of MM. Dulong and Petit, it is found that, if it were possible to obtain the absolute loss of heat which a body in vacuo experiences (or that loss which would take place if there were no restoration of heat from surrounding bodies), the velocities of cooling, estimated by the diminutions of temperature indicated by an air thermometer, would increase in a geometrical progression when the temperature of the heated body increases in an arithmetical progression; and further, that the ratio of the former progression (= 1·0077) would be the same for all bodies, whatever might be the state of their surfaces, and whether the temperature of the vacuum remained constant or increased in an arithmetical progression. But, on taking account of the quantity of heat sent back at every instant by the surrounding medium (a quantity which will be constant if the temperature of that medium does not vary), it is found that the velocities of cooling in vacuo increase, for equal increments of temperature, in a geometrical progression whose terms are diminished by a constant quantity, which quantity varies in a geometrical progression when the temperature of the medium varies in an arithmetical progression. By direct experiments on the cooling of heated bodies in air and hydrogen gas, Dulong and Petit determined what Leslie had before ascertained by an indirect process, namely, that the loss of heat when a body is in contact with a gas is independent of the surface of the cooling body. They found also, by experiments on dilated air and carbonic acid at various temperatures, that the velocity with which a body cools from the mere contact with gas (when the excess of temperature of the heated body above that of the surrounding gas is constant) depends on the density and temperature of that gas; but this dependence is such that the velocity of cooling remains the same if those elements change in such a way that the elasticity of the gas remains constant. The same chemists have also ascertained that, when the elasticity of air varies in a geometrical progression, its cooling power varies likewise in a geometrical progression, in such a manner, that when the common ratio of the first progression is 2, that of the latter is 1·366. If, instead of common air, hydrogen gas, carbonic acid, or olefiant gas be in contact with the heated body, the ratio of the first progression being as before, that of the second is 1·301. And they conclude that the cooling power of each of the last-mentioned gases is nearly proportional to the square root of the elasticity of the gas. ('Annales de Chimie,' vii.; 'Annals of Philos.', xiii.)

That the colours of bodies have some effect on the velocity of radiation and on the absorption of heat has been proved by experiments made by Dr. Stark of Edinburgh (1833). This gentleman surrounded the bulb of a thermometer successively with equal weights of black, red, and white wool, and placed it in a glass tube, which was heated to the temperature of 180° by immersion in hot water; the tube was then cooled down to 50° by immersion in cold water, and the several times of cooling were respectively 21, 26, and 27 minutes. On winding successively black, red, and white wool about the bulb, and raising the temperature from 50° to 170°, the times in which the thermometer so surrounded acquired the latter temperature were respectively 4½, 5½, and 8 minutes. (Turner's 'Elements of Chemistry,' Heat.) Mr. Glaisher ('Phil. Trans.' 1847) found the order of the radiating power of coloured wools exposed to a clear nocturnal sky to be *black, green, white, crimson, scarlet, orange, yellow, dark blue, light blue*, the difference between light blue and black being 1°·3.

The refrangibility of heat was first examined by Dr. (afterwards Sir William) Herschel, who, having analysed by the prism, as usual, a beam of solar light, and having placed a Fahrenheit's thermometer successively within the fields of the different coloured rays in the spectrum, found that in the violet rays the temperature was 2°, and, gradually increasing towards the other extremity, in the red rays it was 7° above the general temperature of the apartment. He also ascertained that there was a point beyond the limits of the visible red rays at which the excess of temperature was a maximum. Similar observations were made about the same time by Sir Henry Englefield; and it was hence evident, not only that the calorific rays were refrangible, but that the property existed in them in a higher degree than in light. Dr. Herschel afterwards made a number of observations on small pencils of heat proceeding from a lighted candle, a common fire, iron heated to redness, and also from iron heated to a lower degree; and he discovered that, in all these cases, the calorific rays were susceptible of refraction. He found however that there was some difference between the heat of the sun and that of terrestrial bodies, the former passing more freely through the glass than the latter. ('Phil Trans.', 1800.) M. Melloni has subsequently ascertained, by using prisms of rock-salt (a mineral which possesses in a high degree the power of transmitting heat), that heat from different sources, like light of different colours, has different degrees of refrangibility.

In the experiments on radiant heat it has been noticed, that when such heat from whatever source has been once absorbed and again radiated it does not retain the peculiarities of its source. But heat of low refrangibility may be converted into that of higher refrangibility.

M. Berard ascertained that when light suffers double refraction in Iceland spar, the two pencils formed spectra which exhibited similar properties; in both, the calorific power differed at the two ends, and existed beyond the visible red rays. Also, on polarising by reflection from glass a beam of solar light, and receiving the reflected ray on a second glass, the latter being capable of turning round till the ray ceased to be reflected from it, he found that while the light was reflected, the heat was also reflected, and that when no light was reflected, there was no heat. The like effect was produced when, instead of a pencil of solar light a portion of radiant heat from a body not luminous was employed, and the inference is, that the particles of radiant heat are polarised by reflection, like those of light. This subject has however been since more completely investigated by Professor Forbes, ('Edinburgh Phil. Trans.', 1835.) Knoblauch, ('Pogg. Annal,' lxxiv.) has also obtained distinct evidence of the diffraction and interference of the rays of heat.

The subject of solar radiation, or of the direct force of the sun's rays, so important to the agriculturist as well as to the philosopher, was treated by Mr. Daniell, in his 'Meteorological Essays,' 1823. On comparing a thermometer exposed to the action of the sun with one which gave the mean temperature of the air in the shade, Mr. Daniell observed that the power of solar radiation varies with the sun's declination; the greatest intensity taking place in June, though the greatest mean temperature of the atmosphere does not occur till July. He observed also that the radiation varies at different hours of the day, increasing with the sun's altitude till a short time after it arrives on the meridian, and then diminishing till the evening. From the observations of Major Sabine at Sierra Leone, at Bahia, and at Port Royal, Daniell was led to conclude that the intensity of solar radiation diminishes in proceeding towards the equator; and the conclusion appears to have been subsequently confirmed by the observations of Scoresby and Parry, and of Richardson, in the Arctic regions. From the observations of Sabine on the mountains of Jamaica, Daniell considers that this radiation increases from the surface of the earth upwards. [Actinometer.]

Since all bodies, even in vacuo, lose heat by radiation, it is easy to conceive that any part of the earth's surface, when not exposed to the direct action of the sun, must emit calorific rays of heat towards the heavens, and thus must become cooled. This is called *terrestrial radiation*, and the subject was particularly considered by Mr. Daniell, who, from observations continued during all the months of the year, found that the maximum depression of the thermometer, on account of radiation, varied from 10° to 17° between midwinter and midsummer; but that the mean depression was the least in January and July, and the greatest in April. It is obvious however that numerous observations are yet to be made in different regions of the earth before any general theory respecting the extent and law of the variations of solar and terrestrial radiations can be formed. The progress that has been made on the subject of late years is noticed under Meteorology; Temperature, Terrestrial, Distribution of.

RADICAL. [Root.]

RADICALS, ORGANIC. [Organic Radicals.]

RADISH. Of this vegetable there are several sorts. The *Scarlet* or *Salmon-coloured*, and the *Radis rose demi-longue*, are the best for early sowing; the latter variety is very tender and of a fine bright colour. The purple, another early long-rooted variety, is sometimes sold under the name of *Salad Radish*, the seed leaves being larger and consequently better adapted for small salading than those of the other varieties. With the colour of the preceding sorts, the *Long White Transparent* will form an agreeable contrast. Of the round or turnip-rooted varieties, the *Early White Turnip-rooted* and the *Purple Turnip-rooted* are the best. The *Yellow Radish* succeeds in hot weather, being fit for use when the earlier kinds are apt to run to seed; and it precedes the autumn and winter varieties, of which the following is the order of succession: *Round Brown, White Spanish, Oblong Brown, Black Spanish*, and *Purple Spanish*. None of these are however esteemed in this country, where they are generally unknown.

If the early white turnip-radish be sown in August, it will come into use in the spring. The principal sowings should however be made in January and February, and successionally till May. The winter varieties require to be sown in July. In cold frosty weather the beds should be protected by straw, as is commonly practised, or by such other efficient means as may be at command. The covering should be always dispensed with when the days are fine; but it ought to be replaced before the cold of night ensues. With careful management they may be gathered nearly throughout the year, but in a hot autumn it is difficult. Radish seed-pods are sometimes pickled, whilst tender, and may be used instead of capers, when the latter cannot be obtained.

RADIUS (a ray, the spoke of a wheel) means the line drawn from a point, considered as a centre or pole, to any point of a curve.

RADIUS OF CURVATURE. [Curvature; Surface.]

RADIX (root) is applied to any number which is arbitrarily made the fundamental number of any system. Thus ten is the radix of the decimal system of numeration, and the radix of the common system of logarithms. The term however has not acquired much fixed use, though often convenient for temporary specification of the use which is made of a particular number or fraction.

RAGGED AND INDUSTRIAL SCHOOLS; REFUGES FOR DESTITUTE CHILDREN. Efforts to instruct ignorant and neglected children are not peculiar to the present time, although such efforts have been of late years more systematic and sustained than formerly. The Sunday schools now so numerous in this country commenced with what were in effect ragged schools. About sixty years ago, Thomas Cranfield, in conjunction with a few other persons connected with Surrey Chapel (Rev. Rowland Hill's), commenced a "Fragment school" in the Mint, Southwark, which was followed by the opening of other schools, similar to the present ragged schools. John Pounds, a cobbler, of Portsmouth, gathered neglected children into his workshop, and in this humble way was able to impart the rudiments of education to about five hundred children. About 1839, efforts were put forth in Bristol and in London to establish schools for the neglected and outcast. Andrew Walker, an agent of the London City Mission, opened schools of the kind referred to in Westminster, and similar schools were soon after commenced in other parts of London, till, in the course of five years, when the Ragged School Union was formed (1844), there were 20 schools, with 200 voluntary teachers and about 2000 scholars.

Ragged Schools are generally intended to impart instruction, chiefly religious. At first they were usually open during the week in the evening only, besides being open on Sundays. It was considered best to commence the experiment with the evening school, as many of the children had to provide for themselves the means of living by selling articles in the streets, and most of them were unwilling to submit to the restraint of school hours during the day-time. This system was found, in the course of a few years' experience, to work very imperfectly, and paid teachers were in many cases engaged to conduc the schools. Such schools were opened during the day as well as in the evening. In many schools industrial day and evening classes were also added; and in some, food, to a small extent, was given to the scholars. In order to obtain more complete control over the children, *Industrial Feeding Schools* were established, in which the children are taken charge of for the whole of the day, supplied with food, instructed in the ordinary branches of common school education, and taught some handicraft. The credit of originating this system is by common consent awarded to Sheriff Watson, of Aberdeen, and the schools founded by him are generally regarded as models. *Refuges* are industrial feeding schools in which the children are also housed and clothed. *Reformatories* are similar to refuges, with this difference, that the children received into reformatories are such as have brought themselves under the operation of the criminal laws of the country, and are, by authority of the magistrates, placed under instruction and discipline, not only for their own benefit, but likewise for the protection of the community. [Reformatories.]

In connection with the London Ragged School Union, at the commencement of 1860 the number of schools held on Sunday afternoon and evening was about 200; of scholars, more than 22,000. Of day schools, there were 146; of night schools, 200. Of industrial classes, there were 114. About 1500 children were sent to situations during the year 1859. There were 2670 voluntary teachers, 380 paid monitors, and 416 paid teachers. The paid teachers have an association for mutual benefit, by means of which new modes of teaching and other improvements are communicated to the members. There were 76 penny banks, with upwards of 15,000 depositors, with an amount approaching 9000*l.* paid in during 1859. In 49 clothing clubs sums amounting to nearly 600*l.* were contributed by the subscribers for the purchase of articles of wearing apparel. In connection with the operations of the Union, there were 93 Ragged Church and City Mission meetings held weekly, and 75 meetings for the benefit specially of the fathers and mothers of the children attending ragged schools. During the year, 132 scholars had become voluntary teachers, and 88 were received as members of Christian churches. The aggregate income of 155 schools for 1859 was upwards of 17,000*l.*, and that of 15 refuges was more than 15,000*l.* The expenditure of the Ragged School Union was about 5000*l.* During the year, 282*l.* 13*s.* had been given by the Union in small sums as prizes to scholars who had retained situations for more than twelve months.

The Western division of the metropolis contains 39 ragged schools, with upwards of 4200 children. Of these schools, 8 are in Westminster, 5 in Chelsea, 1 in Brompton, 5 in Paddington, 2 in Bayswater, 5 at Notting Hill, and 2 at Hammersmith.

The Central and Northern division comprises 38 schools, with about 5500 children. These schools are pretty equally distributed over the district, which is an extensive one, reaching from Bedfordbury, Covent Garden, to Hoxton, and from Clare Market to Agar Town. Five of the schools are in the vicinity of Drury Lane and Lincoln's Inn Fields; 2 in and near Seven Dials; 5 in Field Lane, Saffron Hill, and Clerkenwell Green; 3 in Camden Town; and 10 in Islington.

The Eastern division includes 38 schools, with about 6000 scholars. Of these schools, 2 are in the City, 5 in Whitechapel, 7 in Spitalfields, 4 in Bethnal Green, and 10 in the neighbourhood of the Docks, Ratcliffe Highway, Shadwell, and Poplar.

In the Southern division are 40 schools, with about 5500 children. Two of these schools are situated in Lambeth; 3 in the vicinity of the New Cut; 7 in the Borough; 4 in Newington and Walworth; 5 in Bermondsey; 6 in Rotherhithe, Deptford, Greenwich, and Blackheath; 2 at Peckham; 2 in Camberwell and Brixton; and 2 at Clapham.

Bristol was amongst the foremost in dealing with an unhappy juvenile population by the agency of the ragged school. The name of Miss Carpenter, as a writer and as an active worker, is necessarily associated with this good work in the city where she resides. Few persons have done more to advocate the claims of the children of the ragged school than this energetic and benevolent lady. The Bristol ragged school for males and females, established in 1846, has accommodation for 150; the Bristol industrial school for males, established in 1849, for 50. At *Liverpool* the first ragged school was established in 1844. In 1848 a Ragged School Union was formed. This union comprised, at the commencement of the year 1860, 60 schools, of which 33 were evening schools, 12 day ragged schools, 3 industrial schools, and 12 Sunday schools only. The aggregate attendance of scholars was 6974; the number of teachers 483; and of monitors (in the day ragged schools) 20. During the year 489 obtained situations. In eight of the evening schools, at which the aggregate attendance was 378, a charge of a penny a week is made to the scholars, who are generally ragged school children who have gone to situations. Several of the schools have penny banks in connection with them. *York* industrial ragged school, commenced in 1846, has accommodation for 100 orphans, destitute children, and vagrants. *Manchester* possesses a ragged and industrial school at Ardwick Green, commenced in 1846, with accommodation for 300 poor and vagrant children and unconvicted juvenile thieves, from which, since its commencement, about 500 children have gone into situations. In connection with the Manchester and Salford Ragged School Union, formed in 1858, there are 15 schools, with an average attendance on the Sunday evenings for the year 1859 of 3564 children, with 426 teachers. Each school has one or more evenings in the week devoted to secular instruction, with attendance, in all, of 1916. During the year more than 200 scholars were transferred to Sunday-schools of a higher class; 60 were sent to day-schools, and 65 obtained situations. The penny banks connected with the schools received upwards of 200*l.* from nearly 1200 depositors. In *Birmingham* a ragged and industrial school was commenced in 1846. The free industrial school, commenced in 1849, provides for 120 children of both sexes. *Bath* established industrial schools in 1848; *Derby, Hull, Ipswich,* and *Sunderland* in 1849; *Cambridge* in 1850; *Chester, Clifton,* and *Gloucester* in 1852; *Bolton* in 1853; and others followed in quick succession. At *Bradford*, where the first ragged school was established in 1855, there were in that year 111 cases of juvenile delinquency. In 1856 the number fell to 76; in 1857 to 47; and in 1858 to 26. These results are ascribed to the operation of the ragged school.

In Scotland the subject of juvenile delinquency was first dealt with in the city of Aberdeen, where vagrancy and street begging, with their usual accompaniment of petty pilfering, had become formidable nuisances. With 100*l.* subscribed by himself and some friends Sheriff Watson commenced in October, 1841, an industrial school for boys. The number of scholars at starting was 20. Two years later a similar school was opened for girls. Another, called Sheriff Watson's Female School of Industry was opened in April, 1847, with 53 children. The juvenile school of industry was commenced in 1845, in co-operation with the police authorities, who underook to send to the school every child found begging in the streets. At the end of 1846 was instituted the Child's Asylum, the committee of which investigates the cases of begging and delinquent children, and hears applications from parties for the admission of destitute children into the schools of industry. The children are instructed in reading, writing, arithmetic, geography, geology, and religious knowledge. The boys are employed in net-making, which is found to be a healthy as well as a remunerative occupation; and they occasionally work in the garden. In the girls' schools the scholars do all the household work; they receive an education similar to that which the boys receive; and they are trained for domestic service. The present state of the Aberdeen industrial schools is as follows:—

Schools.	Average Number on Roll.	Average Monthly Attendance.	Average Cost of each Child during the Year.
			£ s. d.
Boys' industrial school	79	70	3 12 6
Juvenile industrial school, boys	67	62	3 18 0
Juvenile industrial school, girls	60	58	
Female school of industry	100	95	4 2 10
Sheriff Watson's female school of industry	63	56	4 15 3½

It is scarcely necessary to remark that juvenile begging has been entirely got rid of in Aberdeen, and that the number of juvenile criminals is very greatly reduced. In 1841 the number of juvenile offenders in prison was 61; in 1858 it was 15. Upwards of 3000 children have attended the Aberdeen industrial schools since their commencement. Of these 200 girls have gone from school into domestic service, and 400 boys into situations, and are, with few exceptions, known to be doing well: many have been taken home by their parents.

The *Dundee* industrial school, accommodating 200 boys, was founded in 1846, and has been extremely beneficial to that town. *Glasgow* commenced the work in 1847, and has six industrial and reformatory schools, with accommodation for more than 1000 children. The Act 17 & 18 Vict. cap. 74, applicable to Scotland, which was passed in 1854, provides that children, apparently under 14 years of age, found in a state of vagrancy, may be brought before a magistrate, and sent to an industrial school. This Act, commonly known as 'Dunlop's Act,' has been found exceedingly useful in Glasgow, as well as in other large towns in Scotland. It has been ascertained that the amount of juvenile begging has been materially lessened since the Act referred to was brought into operation. The industrial school at *Ayr* was founded in 1848; those of *Greenock* and *Stirling* were commenced in 1849; of *Kilmarnock, Paisley,* and *Stranraer* in 1850; and many others have been opened since.

The industrial schools of *Edinburgh* owe their formation chiefly to the exertions of the Rev. Dr. Guthrie of that city. The success of the efforts at Aberdeen and Dundee prompted Dr. Guthrie to take measures for forming an industrial feeding school in Edinburgh. An interim committee was formed, and public attention and sympathy were engaged by the publication of Dr. Guthrie's first 'Plea for Ragged Schools.' The scheme received general support, and was speedily put in operation. Another industrial school was also commenced by other influential persons in Edinburgh. Dr. Guthrie's first 'Plea' was followed by a second, and the two have been recently republished with a third 'Plea,' under the significant title of 'Seed-Time and Harvest; or Pleas for Ragged Schools.' The results in the decrease of juvenile mendicancy and crime have been most striking and satisfactory. From the Original Ragged Schools, 536 have been sent to situations, including those who have been sent out as emigrants, and those who have gone into the army and the navy; from the United Industrial Schools, 461.

About three years ago, cards of invitation to a tea-meeting were issued to as many of the old scholars of the Original Ragged Schools as could be found in Edinburgh. It was a very pleasant and joyous assemblage. About 150 attended, some of the guests being the wives, and others the husbands, of former scholars. Dr. Guthrie says: "We lingered over the scene. Nor could I look on that gathering of young men and women—so respectably clad, and wearing such an air of decency—and think what, but for the ragged school, they would have been, without tears of joy, gratitude to God, welling up to the eyes. It was a sight worth living for. It was our harvest home."

In Ireland not many ragged schools have been instituted, and most of the industrial institutions now in operation are of recent establishment.

The Mill Street ragged school in Dublin was commenced in 1851. Up to 1858 the average attendance of children at the Sunday schools varied from 149 in one year to 360 in another; in 1858 the number was 110. At the daily school for boys and girls, the average attendance varied from 60 in 1851 to 80 in 1858. A ragged school, dormitory, and industrial home for boys, was commenced in 1853, for the benefit especially of destitute and homeless boys attending the ragged school. During 1859 there were 75 boys admitted; of these 22 went to situations.

The following *Refuges*, in connection with the London Ragged School Union, had a total of 605 inmates in March, 1860. The figures appended indicate the number of children in the respective refuges:—

For boys:—Belvedere Crescent, Lambeth, 19; Bridge House, Wandsworth, 70; Britannia Court, King's Cross, 14; Brook Street, Hampstead Road, 18; Bryan Street, Caledonian Road, 32; Euston Road, 51; Great Queen Street, Lincoln's Inn, 100; Grotto Passage, High Street, Marylebone, 22; Hatton Street, Maida Hill, 28; Mansell Street, Whitechapel, 47: total, 401.

For girls:—Albert Street, Mile End New Town, 38; Broad Street, St. Giles's, 52; Hill Street, Dorset Square, 60; Lisson Street, Paddington, 33; Manor Street, Chelsea, 21: total, 204.

From these refuges, during the year, 182 obtained situations, 49 were sent out as emigrants, and 80 were otherwise provided for. A new Home of Industry for Females was opened in October, 1860, at Old Pye Street, Westminster.

The largest Refuge in the metropolis is that in Great Queen Street, Lincoln's Inn Fields, entitled the St. Giles and St. George, Bloomsbury, Refuge for Homeless and Destitute Boys. It was commenced in 1852, in Arthur Street, St. Giles's, with about 20 boys. In 1858 it was removed to extensive premises in Great Queen Street, formerly occupied as a coach factory. The number of boys at present in the house is about 100. They are employed in shoemaking, tailoring and other handicrafts, the return for which lessens the expense of the boys' maintenance. The same society has a refuge for 50 girls in Broad Street, Bloomsbury, and supports several ragged schools. The total number of children admitted into the two refuges up to the end of 1859 was 781; namely, 469 boys and 312 girls. Of the boys, 89 emigrated to Australia, Canada, the United States, and South Africa; 34 entered the navy; 15 entered the merchant service; 76 were placed in situations; 41 were restored to their parents and friends; 2 were apprenticed; and 3 enlisted. Of the girls, 99 were sent to service, 88 were restored to their friends, 13 removed to other institutions, 5 emigrated to Australia, 26 to Canada, 16 to New Zealand. Numerous and satisfactory communications have been received from and respecting the emigrants. Connected with the boys' refuge is a Band of Hope, the members of which are instructed in the principles of temperance, and are trained in singing, in which many of the boys attain great proficiency, and several obtained silver medals in a public competition for singing and recitation.

A source of great anxiety to the conductors of ragged schools is the disposal of the children after they have been in some degree fitted for active life; and emigration, assisted as this has been to a large extent by the government and by private benevolence, has opened an eligible outlet for many hundreds of the children. Many encouraging reports have been received respecting the conduct of the emigrants. Mr. John McGregor, barrister, who has taken a deep interest in all the efforts for the benefit of ragged school children, visited Canada in the autumn of 1858, and made it his business to institute personal inquiries into the condition of boys who had been sent out as emigrants from metropolitan refuges and ragged schools. The result of his inquiries was extremely favourable, many of the boys being found in good situations, and conducting themselves in a creditable manner. The letters from emigrants which are published in the annual reports of the Red Hill Reformatory, the St. Giles's Refuge, and similar institutions, contain much that is interesting and indicative of well-doing on the part of the writers.

An excellent initiatory step in industrial training has been found in connection with the shoe-black brigades. The shoe-black societies were commenced in 1851. For the year 1859 the statistics of those in London were as follows:—

Name of Society.	Uniform.	No. of Boys.	Earnings.
			£
Ragged School Shoe-black Society .	Red.	59	1,746
East London	Blue.	106	1,094
South London	Yellow.	40	669
North-West London . . .	White.	16	140
West Kent	Green.	13	120
West London	Purple.	15	206
Islington	Brown (red facing)	26	240
Notting Hill	Blue (red facing)	26	200
Union Jack (Limehouse) . . .	Red (blue facing)	18	133
		319	4,548

Besides these societies there is a Roman Catholic brigade, designated as that of St. Vincent de Paul.

The result of the establishment and extension of the ragged school system may be summed up in the terms of a resolution, moved by Sir J. P. Kaye Shuttleworth, at a meeting of the Leeds Ragged School and Shoe-Black Brigade, in October, 1860, with Viscount Palmerston, prime minister of England, in the chair:—"The establishment of ragged schools has been productive of much good in diminishing crime and ignorance; and a large extension of this species of benevolence is imperatively demanded in our large and populous towns and cities."

RAGS. Until some better and cheaper material can be discovered, linen and cotton rags will continue to be the staple of the Paper Manufacture, as described in the article under that name, and will continue to be an object of great solicitude to governments and manufacturers. Linen rags are imported mostly from Hamburg, Bremen, Rostock, Ancona, Leghorn, Messina, Palermo, and Trieste. Those from the first three ports are mostly German rags; those from the next four are Italian and Sicilian rags; while Hungarian rags are shipped at Trieste. The rags are closely packed in bags of about 4 cwt. each; and the bags are marked according to quality. The foreign rags are darker, dirtier, and coarser than English; but as they comprise a larger ratio of linen and a smaller of cotton, they are better for the paper-maker's purposes than English rags—especially as they can now be bleached as white as the latter by boiling in a ley, and then exposure to chlorine. Holland, Belgium, Spain, and Portugal, as a means of protecting the paper-manufacture, prohibit the exportation of rags altogether; and France is only now (1860) beginning to depart from that system, as one of the counterbalances for the advantages she receives through the new Commercial treaty with England. The United States compete seriously with England for the purchase of European rags, and overbid her for those of Northern Italy. Taking an average of recent years, the price paid by English paper-makers for foreign rags ranges between 20*l.* and 30*l.* per ton, including freight. When England made 120,000,000 lbs. of paper annually, she used 10,000 tons of foreign rags; if the same ratio prevails now, when the product reaches 210,000,000 lbs. (as it did in 1859), the foreign rags must be nearly 20,000 tons; but there are reasons for thinking that the English portion of the supply, owing to the greater use of cotton and straw, has increased faster than the foreign.

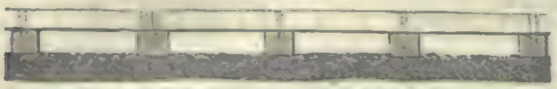
Woollen rags are not available for paper-making. If of loose texture and not too much worn, they are reserved for *shoddy*; that is, they are torn up by machinery into fibres, and mixed with new wool to make cheap woollen cloths. Some of the *pilot* cloths, as they are called, now made in enormous quantities about the neighbourhood of Dewsbury and Batley, consist of three-fourths or seven-eighths shoddy, with only a small proportion of new wool. Some of the woollen rags are made into flocks for beds, by washing, grinding, tearing, and pulping. All that is too bad for these purposes is used as manure. Besides our own woollen rags, the chief foreign supply is from Hamburg and Bremen. The prices are generally about 15*l.* or 20*l.* per ton for good white, 10*l.* or 12*l.* for good coloured, and 5*l.* or 6*l.* for common.

RAILWAY. A road in which smooth tracks of wood, iron, stone, or other suitable materials are introduced for the purpose of obviating the friction of the wheels of the carriages to a greater extent than can be done on common roads. Railways are thus of various kinds, and they have been used for a very considerable time as a means of diminishing the cost of transport of minerals and of heavy goods. Of late years they have been applied to the general purposes of intercommunication, in conjunction with the locomotive engine, and the improvement in all social relations thus effected has been so great, that it has almost formed a new era in the history of our race.

As the construction of railway carriages, and of the engine power employed for moving them, are subjects intimately connected with the formation of the road itself, and indeed regulate some of its most important details, it appears desirable to discuss them at the same time as the railway itself is under consideration. It is intended, therefore, to present a brief sketch of the progress of invention in matters connected with railways; an account of the general mode of designing and executing the works of the substructure, and of the roadway; an account of the usual modes of working a line of railway; and a few of the statistics of the railways already executed at home or abroad.

History.—In the cities of Northern Italy the practice of laying smooth tracks of hard marble in the ordinary paving of the streets, which prevails in those cities to the present day, appears to have been applied for many centuries; but the use of railways, properly speaking, cannot be traced farther back than to about the year 1680, when, in the neighbourhood of Newcastle-upon-Tyne, some roads with wooden rails were laid down (*figs.* 1 and 2), for the purpose of facilitating the transport of coals from the pits to the landing stages. For many years this imperfect system of road making continued in use without improvement, and it was not until about the year 1716 that a raised rail, protected by flat iron on its upper surface, was introduced in those parts of the road where the traction was the heaviest. The next improvement consisted in the substitution of the edge rail for the flat band screwed down to the wood, and the durability of these rails was further increased by the use of cast- instead of wrought-iron. The waggons which ran upon these rails were usually loaded to the extent of from two to three tons, and the traction was performed almost entirely by horses, unless, in a few cases, wherein the carriages were allowed to descend some inclined planes by the effect of gravity. The introduction of the cast-iron edge rail appears to have taken place about the year 1767, at the suggestion of Mr. Reynolds, the engineer of the first cast-iron bridge erected in England, in the Colebrook Dale.

Fig. 1.



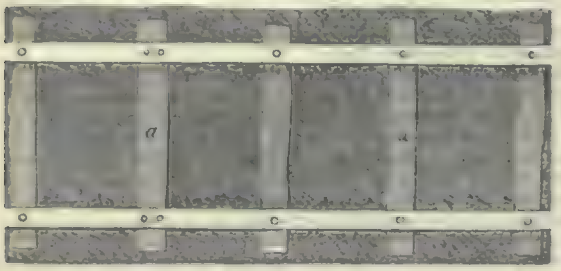


Fig. 2.

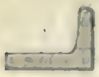
Fig. 3.



The next step in the history of railways was made by the application of a cast-iron plate in a kind of ⌟ form, instead of the straight cast-iron edge rail (*fig.* 3); this alteration was said to have been suggested by the manager of the Duke of Norfolk's collieries near Sheffield, in 1776, and the system itself is still retained in mining operations. The rails, in all the forms originally applied, were laid upon wooden sleepers (*fig.* 4); but about 1793, stone blocks were used to support the rail, and this apparently unimportant change, by rendering the first cost of an edge railway, and its subsequent repairs, less expensive than before, tended greatly to facilitate the introduction of the new system. Very shortly after the substitution of the stone blocks for the wood sleepers, the coalowners of Northumberland and Durham introduced the use of cast-iron edge rails in short lengths, but fastened to chairs let into the stone blocks; and in this manner they succeeded in obtaining a roadway upon which the traction was comparatively easy, at a very trifling expense (*figs.* 5 and 6). The rails were cast in lengths of from 3 to 4 feet, and they were made in what is called the *fish-bellied* form, or with their greatest depth in the middle; *a* represents (*fig.* 5) the section of the rail in the middle, and *b* the section at the ends; the latter were made with a half-lap joint, and through this joint a key was passed to fasten them to the chairs. The friction upon these edge rails was further diminished by making the tires of the wheels slightly conical. Many of the mine railways are even at the present day made precisely in this manner; and so great was found to be the advantage the cast-iron edge rails produced, that several roads were laid down in various parts of the kingdom, about the beginning of this century, in which they were employed. The old Croydon railway, and the tramway laid down in the Commercial Road, London, may indeed be referred to as illustrations of the importance attached by our immediate predecessors to the necessity for diminishing the cost of goods traffic, and of the earnestness of their efforts to attain such results. Animal power was, however, the only one used until about 1810; so that the rapidity of intercommunication could hardly have been much affected by any of the systems applied up to that period.

Fig. 4.

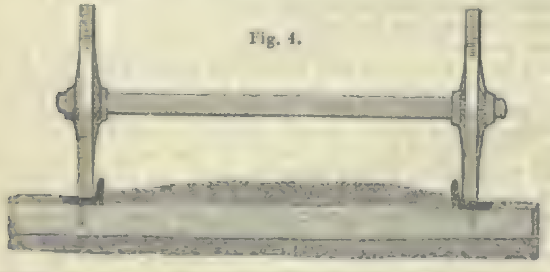


Fig. 5.

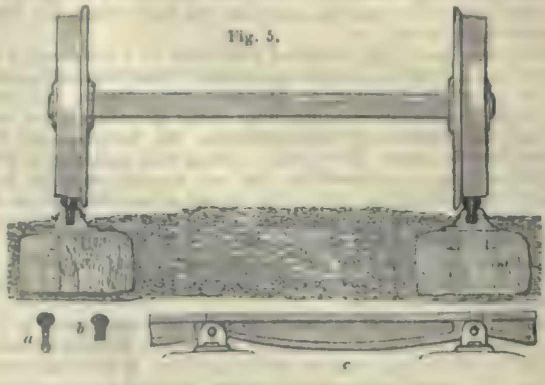

Fig. 6.

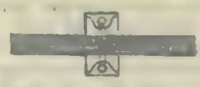
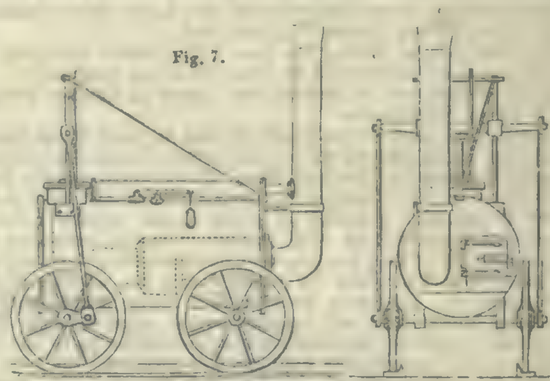


Although the application of steam, as a motive power to the carriages running upon railways, has been of a comparatively-speaking recent introduction, the efforts of mechanicians had long been turned towards that object. Watt, Symington, Trevithick, Blenkinsop, Chapman, Brunton, and others, had striven for more than forty years to discover the means of propelling carriages by steam upon common turnpike roads, or upon railways; but after numerous failures, the whole class of machine-makers seem, about the year 1812, to have arrived at the conviction that a simple band wheel could not exercise a sufficient amount of friction upon a road surface to cause the carriage to advance. For many years the efforts of steam-carriage builders were directed to obviating this imaginary difficulty, and rachet wheels, jointed levers, mechanical legs of every shape and form, were introduced, to the detriment of the roadway, and to the diminution of the useful power of the engine. About 1814, however, George Stephenson constructed for the Killingworth Colliery, Durham, a steam-engine, bearing two cylinders seated upon a boiler mounted on wheels, and immediately above the axles of those wheels, which bore cranks connected with the piston heads of the cylinders, and were made to revolve in unison by means of vaucanson chains working over barrels on the respective axles. The engines made upon Stephenson's principles were not at first much esteemed, and it was long before they became of general use; but gradually they were adopted in the colliery districts; and about the year 1826, Stephenson even applied one of them for passenger traffic on the Stockton and Darlington line. The velocity attained by these engines was not more than about nine miles an hour, when used for passenger traffic; or than five miles per hour for goods.

Fig. 7.

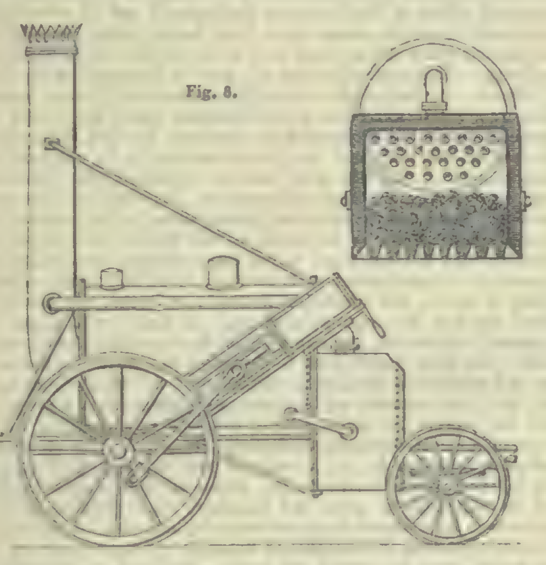


Trevithick's Engine.

One of the great inconveniences felt in the early days of the use of the locomotive, arose from the number and the insecurity of the joints of the rails when the cast-iron fish-bellied ones were employed, and from the brittle nature of the iron itself. The discovery by Mr. Birkenshaw of a mode of efficiently and cheaply rolling malleable iron rails, which was patented by him in 1820, constituted, therefore, a most important link in the chain of mechanical invention, by whose means the railway system has been perfected. The fibrous character of the wrought-iron makes it far less likely to break under concussions than cast-iron would be; and the sectional form generally given to the H or double-headed rail, offers a very great resistance to deflection. It is remarkable that rails which are constantly travelled over do not rust; but it is important that they should be made of a metal as crystalline as it possibly can be, consistently with the retention of its malleability; soft, fibrous iron is, in fact, not suited for the manufacture of rails. Wrought-iron rails are made about 15 or 21 feet in length, instead of 3 or 4 feet, as in the case of the cast-iron rails.

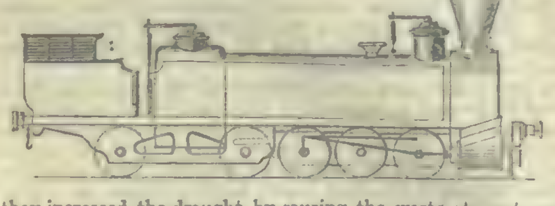
When the projectors of the Liverpool and Manchester Railway were engaged in the design and execution of that great work in the year 1825, and the following years, the capabilities of the locomotive engine were still so little known that it was for a long time a matter of discussion whether or not that description of motive power should be adopted. The directors were soon convinced that horse-power would not enable them to attain the speed they considered necessary; but the result of the experiment upon the Stockton and Darlington line had not been sufficiently decisive to induce them at once to try the new locomotives. They therefore consulted some of the most eminent engineers of the day, and after carefully examining the reports of Messrs. Rastrick and Walker in favour of fixed engines, and those of Messrs. Stephenson and Locke in favour of locomotives, the directors wisely determined to use locomotives, and to offer a premium for the best engine of that description which should fulfil certain conditions. The history of this competition is so well known that it would be useless to repeat it here; and it may suffice to observe that the premium was won by Messrs. Stephenson and Booth, who produced the Rocket engine, of which an illustration is given (*fig.* 8); and thus inaugurated the most important revolution in the means of material civilisation which any age has witnessed. [Stephenson, George, in Biog. Div.]

Fig. 8.



The French mining interest had not neglected to avail themselves of the advantage offered by the edge rails in diminishing the cost of their heavy traffic; and they had constructed about 1826, the railways from Roanne to St. Etienne, and from St. Etienne to Lyon and to Andrezieux. M. Sequin, the engineer of one of these lines, had also constructed some locomotive engines for the purpose of drawing the waggons; and in them he first introduced the use of small tubes passing from the fire-box to the chimney. Messrs. Stephenson and Bury adopted this plan in constructing the boiler of the Rocket, and thus increased in a notable manner the evaporating power of their engine; and they increased the draught by causing the waste steam to escape by the funnel. The cylinders of the Rocket were fixed externally; a system to which after many trials some engine-makers seem disposed to return; and the early locomotives invariably were heated by coke. The Rocket had four wheels, not coupled, and its weight was only 4 tons 5 cwt.; it attained with a gross load of 17 tons, an average speed of 14 miles, and in some instances it attained a speed of 17 miles per hour. It is curious to contrast these figures with the ones connected with the more recent locomotives. Thus, the weight of some of the passenger engines on the North Western line (without their supplies of coke and water) is not less than 27 tons; the weight of some of those on the Great Western line is not less than 31 tons; and some of the engines used on the Sœmering line are even of 48 tons weight and have six coupled wheels. The various considerations connected with the weight and the dimensions of locomotives belong however to the records of the subsequent history of the railway system; its general (or perhaps rather its preliminary) history was closed by the triumphant success of the Rocket.

Fig. 9.



On the modes of designing and executing the works upon railways.—(Organisation.)—It would serve little good purpose to discuss here the question as to whether or not it would be desirable to charge the central administration of a country with the duty of laying out the lines of railway communication; because the peculiar circumstances of every nation will, generally speaking, render the solution of that question independent of any abstract reasoning. No doubt the absence of anything like administrative control has led in England to a fearful waste of money, and to the establishment of a ruinous competition in many instances; but if we had waited until the government had decided upon the merits of railways in the first instance, or until it should have decided the precise routes to be followed by the new lines of intercommunication in the second, it is tolerably certain that we never should have possessed the marvellous instruments of civilisation we actually do. The results of the intervention of the state authorities in other countries do not seem to warrant the belief that, in the end, they manage things better than is done here; and practically it has been shown that the "laisser aller, laissez faire" system conduces the most surely, not only to a nation's greatness, but even to the extent and the perfection of its railways. At any rate our trunk railways are made, and it would be useless now to attempt to retrace our steps. In our colonies there may be reason, and there still is time, for the government to interfere, to guide the efforts of capitalists, and to spare them from the robbery and extortion they certainly have been exposed to in England. But the author of this notice, who has had a long practical experience in foreign countries, feels it at once to be his duty to record his conviction, that no more mischievous course can be adopted than for the government of any country to execute, or to work a railway; either when the question is considered from a structural and engineering point of view, or from a political, or moral one. Perfect freedom of private industry *may* lead to abuses; the creation of a number of places of pay and profit *must* do so, however honest the chiefs of an administration may be.

However the management of the general system of the railways of a country may be settled, the first questions which require consideration, when it has been determined to execute a line between any two important termini are, whether or not it should be made to deflect a little, in order to accommodate the local traffic; or whether it would be preferable to serve that traffic by means of branch lines. The relative importance of the intermediate towns and the, so to speak, locomotive habits of their inhabitants, must be taken into account in arriving at the decision on this subject; as must also be considered the pecuniary circumstances of the local travellers, inasmuch as the latter materially affect the relative proportions of the persons taking the various classes of carriages. On short railways the local traffic will be found to vary between from 60 to 90 per cent. of the whole receipts; on long railways the through traffic bears a larger proportion to the total receipts, and this probably as much on account of the increased number of first-class passengers, as on account of the increased total number of passengers. The usual relative proportions of the travellers in the various descriptions of carriages is in England as follows: in the first class there are about 13·2 per cent., in the second there are 31·2 per cent., and in the third 55·6 per cent.; in Germany these proportions do not hold, for the first-class passengers are fewer, and the second-class ones have a much greater relative importance; these differences may to some extent be explained by the character of the accommodation given, but the comparative wealth of the population to be served must also influence them. The probable amount of the local goods traffic must be taken into account likewise in estimating the influence of any particular place on the prosperity of a line; and above all things an estimate of the cost a passage through it would entail must be made. It would appear that the average distance traversed by a ton of goods on lines of considerable length is about double the distance travelled by ordinary passengers, and that goods travel a relatively greater distance on long lines than they do upon short ones. As a general rule, the result of the most careful investigations of the traffic returns of railways has been to show that it is not desirable to sacrifice local traffic to the interests of the termini; and the history of some of our "direct lines" proves that whenever the communication between the termini is sufficiently important to justify a direct railway, the want will very soon be supplied. There are some curious statistics on this subject in Lardner's 'Railway Economy,' and in Perdonnet's 'Traité Elémentaire des Chemins de Fer.'

The principal points through which a railway is to pass being thus settled, it is necessary carefully to examine the country to be traversed, its relief, its means of transport for the materials required, its rivers, roads, and canals, both on account of the facilities they may furnish, and of the works they may render necessary, and its geological structure, both superficial and subterranean. If this inquiry should not lead to the discovery of any special necessity for carrying the line in a definite direction, it should, of course, be made as straight and with as near an approach to a dead level, as is possible. In the early days of railway making greater importance was attached to the latter condition than is now the case; and in France, even as late as in 1846, Mr. Locke had great difficulty in persuading the authorities to tolerate inclines of a rise of 1 in 126; but upon the Birmingham and Gloucester line, the Lickey incline with a gradient of 1 in 37, has been for years in successful work, and in the passage of the Sœmering, on the Vienna and Trieste railway, the inclines are sometimes carried for great distances, at the rate of 1 in 40, and the radii admitted in the curves upon the level parts are often not more than 623 feet, whilst upon the inclines of 1 in 40 they are still occasionally of only 934 feet; the length of the arcs in the latter cases does not exceed 1300 feet in round numbers. Of course the speed over lines with inclines of so severe a nature cannot be great, but the introduction of the expansion gear into the locomotive has so much increased what may be called the elasticity of its powers, that at the present day an incline of 1 in 100 would not be regarded as unfavourable, and the former limit of 1 in 200 would not be a matter of a moment's hesitation. Curves of 800 feet radius are often resorted to, when, on account of the approach to a station, the speed of a train must be slackened; but it is hardly safe to admit them of a less radius than of about ¼ of a mile on the ordinary parts of the line.

The limits of incline above quoted are the maximum ones which can be worked economically by locomotive power, and whenever it might become necessary to overcome differences of level, which could not so be passed, it would be indispensable to resort either to the use of inclined planes, or to tunnel through the hill which interposes itself. The mechanical principles upon which these considerations mainly turn are, firstly, that upon a railway the traction does not exceed $\frac{1}{7}$th of the effort required to move a load on a level and well-made turnpike road; or as the traction on the latter is as 1 to 30 of the load, it is on a railway as 1 to 210 or to 250; at an inclination of 1 in 250 it is already about as 1 to 100; and it thence rapidly increases until with an inclination of 1 in about 150 a well-made carriage would, if left to itself, descend an incline by the mere effect of gravity; or, in other words, the force required to draw the load up the incline must not only be in excess of that required to overcome the friction, but also to raise a portion of the dead weight of the train. The practical questions connected with the nature of the inclines admissable on a railway, it may be added, may often be materially affected by the use of bank engines upon the heaviest part of the inclines; but however the difficulties of such inclines may be obviated they must always constitute a burden upon the working expenses of a railway, so that they should never be admitted unless at the last extremity. As far as possible alternate directions of inclination should be avoided, and the rise should take place as nearly as may be to some engine station, whence a supplementary engine could be obtained if needed. Curves of small radius are nearly as unfavourable to the economical working of a railway as are heavy inclines, and they therefore should only be resorted to in the last extremity.

The only other special considerations to be taken into account in the laying out the plans of railways are, firstly, that they should cross existing roads as seldom as possible on a level; and secondly, that the stations should be made in positions where they can easily be approached. All that relates to the execution of embankments, bridges, viaducts, culverts under or over passages, resembles so closely the same description of work required in ordinary engineering operations, that they may fairly be discussed under the exclusively practical section of the formation of the road.

Obtaining an Act of Parliament.—As the railways in England are constructed by associations of private individuals, with a view to their own pecuniary advantage, as well as with a view to the public benefit, it is necessary that, on the one hand, legislative restrictions should be imposed to protect the interests of all who may, either directly or indirectly, be affected by the execution of such works; whilst, on the other hand, the promoters of the scheme should be protected against the imposition of the landowners, and should be vested with the necessary powers to carry their scheme into effect, if the legislature should consider it to be advisable. Lands, buildings, water-courses, canals, roads, &c., have from time to time to be interfered with; and whilst justice requires that the various parties interested in them should be fairly and liberally indemnified for any loss accruing to them or to their property, either directly or contingently, and that every unnecessary interference with the existing rights of property should be avoided, it is equally necessary for the public benefit that operations of this description should not be defeated by objections inspired by prejudice, or by mistaken private interest. It has been with a view of reconciling both of these conditions that the Houses of Parliament have issued a code of instructions, known under the name of the *standing orders*, for the purpose of affording the parties interested the means of stating their respective cases before the tribunals appointed to examine the necessity for the legislative powers sought to be obtained; and although there are no doubt instances in which great apparent injury is thus inflicted, on the whole the system of referring railway bills to select committees of the two Houses has (to quote a well-known phrase) "worked well." The opportunity thus afforded for factious opposition is, perhaps, one of the worst evils attending this system of legislation; and it often leads to a frightful expense. The act for the London and Birmingham Railway cost at least 72,000*l.*; that for the Great Western, cost 88,000*l.*; and that for the Brighton Railway, a still larger sum. The standing orders and the legislation of railway companies have been frequently modified; but at the present day they may be stated to be (briefly) as follows.

Bills for the establishment of a joint-stock company for the execution of a railway, or for the increase of the powers of any existing company, are of the second class of private bills. Notices of the intention to apply to parliament for the necessary powers must be given once in the months of October and November, or in one of them, in the London, Edinburgh, or Dublin Gazette, and in three consecutive weeks in some one and the same newspaper of the county in which the lands such bill refers to may be situated; if the works should extend over more than one county, then the notices must also appear in the journals published in London, Edinburgh, or Dublin, as the case may be. Notices are to be given, in writing, to the landowners, lessees, and occupiers, of the intention to apply for the bill, and these notices must be served before the 15th of December previous to the session in which the application to parliament is to be made. Plans and books of reference of the lands and houses to be taken, together with a section of the intended line, are to be deposited before the 30th of November with the clerk of the peace, or the sheriff clerk, of the respective counties traversed, with the Board of Trade, and at the private bill offices of the Houses of Parliament; and in cases where it is proposed to execute works upon tidal lands, within range of spring tides, similar plans and sections have to be deposited with the Board of Admiralty. The petition for the bill is to be deposited at the Private Bill Offices on or before the 23rd of December, and it must be accompanied by a declaration from a parliamentary agent, and a copy of the proposed bill: in the declaration by the agent, he shall distinctly state the class of the bill, and the powers sought to be obtained by it. Printed copies of the bill must also be deposited with the Board of Trade, on or before the 23rd of December; and with the Admiralty, if necessary. Copies of the estimates, declarations, lists of owners, lessees, and occupiers, are to be deposited at the Private Bill Offices on or before the 31st of December; and in cases wherein new companies are proposed to be established, a declaration must be made, stating the amount of capital, the number of shares to be issued, the number subscribed for, and the number paid up. In some cases, copies of the last-named documents are required to be deposited also at the Vote Office. The plans required are to be drawn to a scale of 4 inches to a mile, and must show the line or situation of the whole work, and the lands, &c., it is intended to traverse; and whenever it is proposed to apply for powers to make lateral deviations, the limits of those deviations must be distinctly indicated. Enlarged plans of buildings, court-yards, gardens, &c., to a scale of not less than ¼ of an inch to every 100 feet, must be added; the distances from one of the termini must be indicated in miles and furlongs; those portions of the line which are to be executed in tunnel must be indicated by dotted lines; and every deviation or alteration of turnpike or other roads, of rivers, or of canals, must be clearly set forth. The book of reference must contain the names of the owners, lessees, or occupiers of the houses and lands to be interfered with, and it must contain a description of the nature of the property to be taken. The sections are to be drawn to the same horizontal scale as the plan, and to a vertical scale of not less than one inch to every 100 feet; they must show the natural level of the ground, the intended level of the work, the relative heights of the embankments and cutting, the datum line, and the rails' level; the height and span of the various bridges, viaducts, &c., are to be indicated, as also are to be indicated the alterations proposed to be made in the levels of the existing roads or other communications. The estimate must be signed by the person making it. In the case of railway bills, a deposit of 8 per cent. on the amount of the estimate must be made before the 15th of January.

The details of the preliminary requirements of the legislature, stated above as being necessary before the bill can be entertained, are extracted from the standing orders of the House of Commons; but, according to May's 'Parliamentary Practice,' the requirements of the two Houses are identical, excepting in some insignificant matters of detail. The further stages of the proceedings, it may be added, are described upon the supposition that the bill sought for is presented, firstly, to the House of Commons.

Any person interested in the proposed railway, or in its operation, is entitled to present a memorial in opposition to its progress, on the ground of non-compliance with the standing orders, before some day between the 9th and 23rd of January, according to the number of rotation assigned to the petition for the bill. The examiners of petitions for private bills then inquire into the manner in which the standing orders have been complied with; and, if any irregularity should have been committed, they make a report to the House of Commons, or send a certificate to the House of Lords, to the effect that the standing orders have not been complied with, but they do not at all enter into the inquiry as to the merits of the bill. If the standing orders should, however, have been complied with, a report is made to that effect. Within three days from the date of the indorsement of the bill by the examiner of petitions, the petition for its being read must be presented by a member, and it must be accompanied by a printed copy of the bill; and if the standing orders have been complied with, the bill is at once ordered to be brought in; if they have not been complied with, the petition is referred to the standing orders committee, who are empowered to make special reports to the House on such subjects. The second reading of the bill takes place at some period between the third and seventh day from the first reading, and is considered substantially to sanction, in the opinion of the House, the principle of the bill, which is then committed. It is firstly referred to the general committee on railway and canal bills, which names the chairman and members of the select committee before whom the examination into the allegations of the petition and the clauses of the bill takes place. The select committee must consist of five members not locally or otherwise interested in the bill, when the latter is opposed; or the bill may be referred to the chairman of ways and means and to two members, when it is unopposed. After an interval of eight days at least from the second reading, the select committee proceed to hear the parties who seek the act, and those who have petitioned against the bill, either by themselves, by their agents, or counsel; and after a careful examination of the evidence submitted to them (in the House of Lords the evidence is taken upon oath), the committee are bound to report upon the various subjects involved. These subjects mainly affect the fitness of the proposed railway in an engineering point of view, the peculiar local circumstances affecting the works, and the main allegations of the petitions for or against the bill, with the reasons of the committee for agreeing to or dissenting from them. The committee is bound not to authorise a company to raise a larger sum by loan or mortgage than one-third of the capital; and until 50 per cent. of the capital has been paid up, the company is not to be allowed to raise any loan. No alterations of turnpike roads are to be allowed which should leave the rate of inclination of the new road more than 1 in 30; nor shall any other road be made, without special reason, whose incline shall exceed 1 in 20. Numerous provisions are made also by the instructions of the House for the purpose of preventing any abuse of the powers to be conferred by the bill, or of preventing the smuggling of clauses for one object under cover of a bill avowedly proposed for another one. It is worthy of remark that amongst these instructions, which in fact constitute the standing orders to the committees, there is one whose object it avowedly is to prevent the payment of interest upon deposits, or payments on calls, until the line is opened—a course of proceeding diametrically opposed to the one followed by all other countries in Europe. The usual course of the inquiry before the committee, so as to enable them to make their report to the House, is to discuss firstly the preamble of the bill; and, if that should be declared to be proved, then to discuss the clauses seriatim. In this manner the whole of the measure is capable of being thoroughly examined, and the obnoxious portions can be removed if the parties really interested attend to their own business; the principal difficulty, however, attending all these proceedings lies in their cost.

When the report of the select committee has been made, the committee clerk delivers into the Private Bill Office "the committee bill," which is printed at the expense of the parties, and delivered to the members of the House. The report of the bill is ordered to lie upon the table, as also is the amended bill; and after the interval of three clear days from the delivery of the report the consideration of the bill may be proceeded with, on the third reading. So jealous is our legislature, *theoretically*, of the rights of private property, that it is easy, even at this stage, to stop the progress of a bill; but, in fact, it is very rarely that the decision of a select committee is reversed. The usual course is, that the bill, as it leaves the committee, passes on the third reading; and it then has to go through nearly a similar ordeal in the House of Lords; and, unless important amendments should there be introduced, the bill receives the royal assent, and becomes an Act of Parliament. The proceedings before the House of Lords differ in some respects from those which are followed before the House of Commons; but the differences consist mainly in points of form, and they seem to have been inspired principally by the desire of the former House to protect in the most efficient manner the vested rights of property. The reader who would desire to study more in detail the law and the practice of Parliament in these matters, would do well to consult the work by Mr. May before referred to, and to read the Standing Orders published by the respective Houses of the legislature at the commencement of each session. Amongst other provisions made by the House of Lords, there is one it may be important here to notice—namely, that they fix at the commencement of every session a day beyond which they will not take any proceedings in private bills, whencesoever proceeding. Mr. May's work contains also an ample description of the fees payable to the officers of the respective Houses of Parliament, a study of which might fairly be recommended to the attention of the administrative reformers of the day.

Owing to the numerous subjects embraced, a railway act is always a lengthy document; but of late years these measures have been considerably simplified by the passing of the Railway and of the Lands Clauses Consolidation Acts. In cases where companies simply apply for powers for increasing their capital, or when they apply for powers of amalgamation, or purchase of other companies, the forms of parliamentary practice are slightly different from those above described; and the Wharncliffe standing orders prescribe the observance of certain conditions under the peculiar circumstances they were designed to meet, especially with reference to the manner of ascertaining the opinions of the shareholders of any existing company as to the extension of their operations. The principle of this legislation is, however, on the whole, extremely equitable, and it substantially affords protection to existing interests, whilst it gives every reasonable facility for the development of enterprise.

Formation of the Road.—The Act of Parliament being obtained, the land required for the railway is definitively set out and purchased. Power is usually given to take a width of 22 yards, exclusive of that which is necessary for the sloping sides of cuttings or of embankments; and it may be added that, in ordinary cases, the average quantity of land taken is about at the rate of 12 acres per mile lineal of road, leaving out of account the stations, when the latter are of considerable importance. The price to be paid for the land is either settled by amicable arrangement, or it is fixed by a jury; and it includes all claims for compensation, severance, and compulsory purchase. It appears that, practically, railway companies are compelled to pay about double the real value of all the land or hereditaments they take—so deeply rooted is the popular opinion that the interests of private individuals should be studied at the expense of public companies.

The works themselves connected with the formation of the road consist in the embankments and cuttings, the tunnels, the bridges, viaducts, and culverts, and the stations and minor accessory buildings. These works are usually divided into separate contracts, and are let by public or by private competition, unless when—as is far too often the case in England—the bulk of the capital has to be provided by the contractor. In ordinary cases, the works which would take the longest time are commenced the first, especially when it is desired to open the line at once in its entire length. Before any works, however, are commenced, it is essential to make a series of deep borings wherever important structures are to be raised or tunnels to be formed; the result of the preliminary observations upon the Kilsby Tunnel seem, indeed, to show that these borings should be made very close to one another, and that they should be carried at least to the maximum depth it may be desired hereafter to attain. Careful observations must also be made upon the hydrographical conditions of the country to be traversed, the inclination of the strata, and their hydroscopic nature, not only for the purpose of dealing with the springs they may yield, and their greater or lesser tendency to floods, but also in order to provide against any danger from the slipping of the earth. It must be observed here that tunnels upon railways are objectionable, on account of their darkness, their dampness, and the singular interference they produce with the action of the electrical telegraphs, as well as on account of the special attendance they require. As far, therefore, as possible, they should be avoided; nor should they ever be resorted to in the open country where land can be obtained cheaply, unless the cutting it would otherwise be necessary to make should exceed 80 feet in depth. In towns, of course, the value of land will materially affect this question, and, as in the case of the Underground Railway, it may even be desirable to execute nearly the whole of the line in tunnel. [TUNNEL.]

The angle of inclination of the slopes of cuttings should be made to vary with the nature of the material traversed. Hard limestone or sandstone rocks will stand when dressed off vertically; chalk and the softer limestones will ultimately assume a slope of about 45°, or of 1 base to 1 vertical; hard gravel, bound together by waters containing the hydrous oxide of iron, will stand at a similar inclination to chalk, but the ordinary open gravel and sand, without water, should be dressed to a slope of 1½ base to 1 in vertical height; the London, Oxford, and Gault clays may sometimes stand with an inclination of 2 or 3 to 1, but if they should contain any beds of permeable sand they have been known to slip even with inclinations of 10 to 1. Wherever moveable strata of this description are encountered, the greatest precautions must be taken to provide an efficient surface drainage, so as to prevent the passage of water to the more permeable lower strata. The danger arising from the tendency of some materials to slip after the condition of stability they have naturally assumed has once been disturbed, is principally felt when the cutting has to be made on a hill side, and when it lays bare the lower edges of inclined beds of sand or of gravel intercalated between beds of clay. In many cases, it is better to construct at once a retaining wall than to trust to any form of slope; but the thrust of a lofty bank of earth, such as is now under consideration, must be so enormous that especial precautions must be taken to guard against its effects, and to provide an outlet for the waters which would otherwise accumulate at the base. The history of the New Cross cutting, near London, of the Euston cutting, of the London end of the Great Northern Railway, of the Kilsby cutting, and of the cutting near the Val Fleury, on the Versailles line, may be cited as illustrations of the accidents to which deep cuttings are exposed, and of the means of obviating them. Much information on this subject is to be found in Sganzin's 'Cours de Construction,' and in

Perdonnet's 'Traité' already referred to. In settling the amount of cutting to be executed on a line of railway, it is essential to bear in mind that it should, as nearly as possible, balance the amount of the embankment so as to avoid either the necessity for purchasing ground to receive the spoil or surplus earth, or to furnish the material for the completion of the bank from side-cutting. The Tring cutting on the Birmingham Railway, and the Gadelbach cutting on the Ulm and Augsburg line, are amongst the largest works of this description yet executed: the former contained nearly 1¼ millions of cubic yards; the latter about 1,410,000 cubic yards.

The embankments are formed simultaneously with the cuttings, and the materials obtained from the latter are transported by barrows, carts, or waggons, to the former, according to the distance; barrow-work ceasing to be economical when the distance to be traversed exceeds 100 yards, carts are then used; and when the length of transport attains a quarter of a mile it is decidedly cheaper to use waggons upon temporary roadways, made in railway works of the metals, or rails, to be afterwards used for the permanent way. As embankments can thus only be commenced from their two ends at a time, it follows that when they are of considerable dimensions they may even regulate the duration of the works upon a railway, because bridges or tunnels can be commenced at once in several places. Time may occasionally be saved by the use of temporary wooden staging, and by carrying on the work in several layers or strata; but if the length of lead (or the distance traversed) be great, it is very rarely indeed that more than from 2000 to 2500 yards cube can be tipped at one end of a bank in a day. The earth in small banks is often rammed to ensure its uniform compression, and even in the very rough and ready manner in which railway works are effected, especially in England, the precaution of punning the earth at the back of culverts, or bridges, is generally adopted. For large embankments it would be practically impossible to attempt to secure this theoretical perfection, and the earth is in them simply cast, or tipped, from a waggon, and is allowed to settle by its own weight, and by the effect of time. It is important, therefore, to observe that the earth taken from a cutting will, in the beginning, occupy a space about ⅕ greater in the bank than it did in its natural position; and that even after they have settled during three or four years the materials in a bank will still occupy a volume ⅛th greater than they did originally. The subsidence of new-made banks is indeed a source of danger and of expense on all railways, and it must be guarded against in the most careful manner; allowance should be made for such subsidence, by keeping the crowns of the banks above the intended finished level.

In executing heavy embankments care must also be taken to ensure that the ground upon which they are to be founded should not be exposed to lateral displacement, or to any serious amount of vertical compression; although the latter objection ultimately resolves itself simply into a question of money. Accidents of this description frequently occur upon the banks of rivers, or in alluvial districts; and the most efficient mode of dealing with them is to isolate the seat of the bank from the surrounding ground, in such a manner as to cause the whole compression to take place vertically. In marshy and boggy grounds judicious drainage may do much good; but the system adopted in carrying the Liverpool and Manchester Railway over the Chat Moss, of supporting the earth to be deposited upon a stratum of hurdles, or the one used by the Dutch engineers of forming as it were a floor of fascines, or of bundles of reeds, must in many instances be resorted to in addition to the introduction of lateral drains. On the Munich and Augsburg line an efficient method of carrying the railway embankment over a peat-bog about 16 feet deep was used, which it may perhaps be desirable to mention here; it consisted in sinking a series of square holes, "en echiquier," about 2 ft. 10 in. apart, and measuring 1 ft. 9 in. square at the bottom, and 2 ft. 10 in. square at the top; these holes were then filled with impermeable earth, and the embankment was laid on them; the seating of the bank was first properly drained and a good outfall provided. Another class of positions in which it is necessary to take especial precautions in forming embankments, is when their feet are exposed to the action of large bodies of water, whether tidal, flowing, or comparatively still, as in lakes. The materials used below the water-line should be of the greatest possible specific gravity, the seat of the bank should be cleared, by dredging, of all loose or compressible mud, and the sides exposed to the wash of the water should be protected by beds of fascines, or by stone pitching in ordinary cases; in sea water, or in open bays, it may even be necessary to carry the foot of the embankment upon solid masonry walls. [EMBANKMENT; RIVER; WEIR.]

The earth-works upon most of the principal lines in England have been very heavy, and they seem in some exceptional cases even to have cost 20,000*l.* or 30,000*l.* per mile; nor has it been by any means rare for the average cubical quantity of earth so moved to average from 100,000 to 150,000 yards per mile. In other countries this portion of the cost of railways has been diminished; first, by reason of the lower price of labour; but secondly and principally, by reason of the facilities afforded by the steeper gradients now tolerated.

There are some minor works usually included in the description of the excavator's department in the construction of a railway, which are of sufficient importance to require notice. These are the fencing in of the land; the formation of the cop mound, and of the ditch; the planting of the quickset hedge; and the soiling and planting of the slopes. Insignificant as these works may seem to be in themselves, much of the security from accidents of the railway depends upon their being well executed and well maintained; and it is especially on account of habitual disregard the American engineers display to the safe enclosure of their lines, that the accidents from strayed animals occur so frequently with them. The planting of the slopes of embankments, it may also be added, is an easy and profitable mode of protecting them.

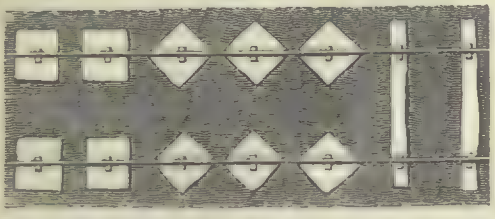
Bridges are required on railways for the purpose of carrying them across the various water-courses; for maintaining the existing road communications either above or below the level of the rails; or for carrying the roadway above the surface of the ground in deep narrow gorges when for local reasons it is found that the construction of viaducts is preferable to the execution of heavy embankments. The choice of the materials used for the construction of railway bridges must mainly be influenced by economical considerations, always bearing in mind the fact that in *under*-bridges the materials used should be of a permanent description; because the repairs of the substratum, so to speak, of a roadway are always attended with difficulty; for *over* bridges wood, brick, stone, or iron may be used as may be found advisable. The reader is referred to the articles BRIDGE and VIADUCT for a detailed notice of the principles of construction required to be followed in this class of works, and under SKEW ARCH and TURNING BRIDGE will be found notices of peculiar forms of bridges frequently employed on railways. It seems that upon the average there are about 2½ over or under road bridges per mile forward of railway in England, even when a considerable number of level crossings are allowed; in England there is at least one crossing per mile. As was before said, the latter should be avoided as much as possible, for they are a frequent source of accidents, and the cost of the guardian represents the interest of a larger sum than an ordinary bridge would cost. It is not often, in fact, that an ordinary over or under bridge costs more than 1000*l.* to 2000*l.*; or perhaps, taking into account the approach roads, the latter figure may be taken as an average; this has to be set against the cost of the cottage, gates, and crossing, and the keeper's wages, in case a level crossing should be resorted to. It is usual to estimate that the cost of culverts, surface, or underground drains of a railway amounts to 20 per cent. of the cost of the under bridges; the cutting of the lateral ditches being carried to the earthworks account. The masonry for lining tunnels, or for retaining walls, forms part of those special items in railway estimates.

When the various works connected with the cuttings and embankments are finished, and the bridges are ready to receive the ballast, the railway is said to be brought to *formation level*, and all that remains to be done is to lay down the permanent way. The formation level is usually made about 2 feet below the intended rails level; the width of its surface is about 30 feet, exclusive of fences and ditches; and it is made higher in the centre than at the sides, in order to throw off the rain water.

Ballasting and laying the permanent way.—In the earlier periods of the history of railways very warm discussions were carried on with respect to the form of rail, and the mode of attaching it to the sleepers or blocks; but at present there seems to be a very marked tendency on the part of engineers to adopt uniformly the system of double-headed rails, keyed to chairs spiked upon cross wooden sleepers, and fish-jointed at the ends. As many useful lessons were learnt in the course of the experiments by which the system now generally adopted was arrived at, and the history of the superstructure of railways is in itself very interesting, a slight notice of the various phases of the discussions in question may be desirable. So much indeed of the commercial success of a railway depends upon the perfection of its permanent way, that it behoves every engineer, at least, to study carefully the phenomena which might have been observed during the respective trials; and it is even desirable that the directors of railway companies should know something of the previously made experiments in this matter so as to avoid a useless repetition of them hereafter.

When locomotive engines travelling at speeds of even nine miles an hour had been introduced, it was soon found that cast-iron fish-bellied rails were so liable to be displaced and fractured that their use was at once abandoned; parallel wrought-iron rails were substituted for them universally. On the Liverpool and Manchester, and on nearly all the railways executed by the Stephensons in the early periods of the railway system, the rails were keyed to chairs, fastened to stone blocks bedded in the ballast; but it was soon found that the blocks, which were isolated from one another, were exposed to sink unequally, and thus to deform the road; and moreover that the unyielding nature of the point of support (when it had once found a bearing) made the roadway very injurious to the carriages and rolling plant. Mr. Locke seems to have been the first to have adopted on a large scale (as the means of obviating these inconveniences) the use of the old system of wooden sleepers, passing beyond the two rails (as shown on *fig.* 10) so as to carry two chairs; and at the present day this system has been generally adopted wherever the rails are used with only occasional supports. Many essays of cast-iron sleepers have been made, without success, it must be added, for in the present state of iron metallurgy cast-iron goods are too brittle to be employed for articles subjected to the peculiar actions to which sleepers are forcedly exposed; but it is still to be hoped that means may be discovered by which this objection may be removed, and that this material, inattackable by insects and comparatively indestructible by atmospheric influences, may be substituted for wood. The rapid decay of the wooden sleepers has, indeed, been always the subject of anxiety to railway engineers; and many patents have been taken out for their preservation. Sleepers have been soaked in solutions of zinc, copper, mercury, &c., with variable success; but at the present day it seems to be generally admitted that creasote is the material which, when properly applied, contributes the most valuable properties to wood so exposed; all these processes are however but palliations of a serious evil inherent to the use of wood, and it certainly would be preferable to employ a material exempt from the conditions of decay above enumerated. However this be, the cast-iron chairs used either for blocks or for sleepers are spiked down with iron spikes, and some trifling modifications of the patterns of the chairs are at times advantageously made in order to avoid the splitting of the fibres of the wood. The rails are fastened to the chairs by means of compressed wooden wedges, which naturally expand again when exposed to the effects of moisture; these wedges are at the present day creasoted on the best lines of railway. Sleepers are usually from 7 to 9 feet long, by 10 in. by 5 in., and are usually placed at distances of 3 feet from centre to centre, on the average; especially on the lines where heavy locomotives are used.

Fig. 10.

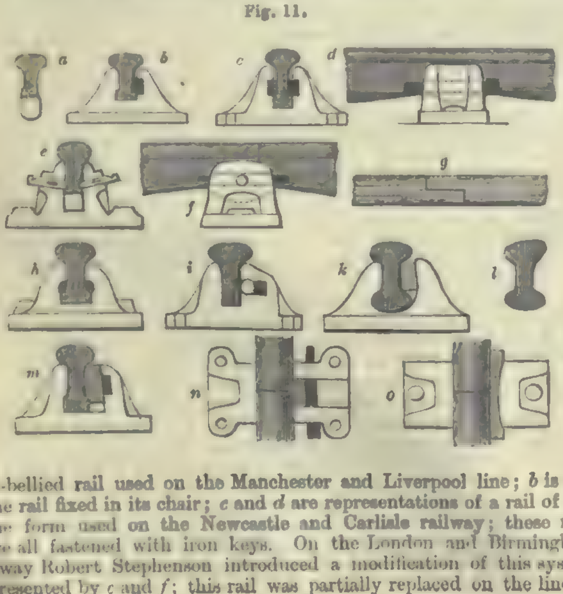


The sleepers, as was said, are laid in ballast, which should as far as possible consist of gravelly sand, sufficiently permeable by water to allow the rain to pass rapidly into the surface, and to the side drains. When, however, ballast of this description cannot be obtained, it may be replaced by sand, by shingle, by broken stones of not more than 2½ inches in diameter, by burnt clay, or by a mixture of chalk and flints; in mining districts forge ashes and broken slag are advantageously used. The ballast is made (for double roads) 30 feet wide and 18 inches thick, on the average; and its surface is dressed off so as to form a series of water-courses. It requires about 8,800 yards cube of ballast per mile forward of railways, or about 5 yards cube per yard lineal.

The form of rail used, and its weight, have passed through many changes, but they have finally resolved themselves into two principal varieties, known as the double-headed rail, and the bridge rail; the latter being employed on lines such as the Great Western, where continuous longitudinal bearings have been adopted instead of the ordinary chairs and sleepers. The advantages and disadvantages of the bridge rail will be discussed hereafter, and for the present, attention will simply be called to the steps which have led to the adoption of the double-headed rail most frequently employed.

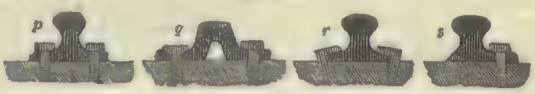
In figure 11, the illustration marked *a*, represents the section of the fish-bellied rail used on the Manchester and Liverpool line; *b* is the same rail fixed in its chair; *c* and *d* are representations of a rail of the same form used on the Newcastle and Carlisle railway; these rails were all fastened with iron keys. On the London and Birmingham railway Robert Stephenson introduced a modification of this system represented by *c* and *f*; this rail was partially replaced on the line of railway just mentioned by the form shown on *h*; and at *i* is shown a contrivance for keeping the rail in its seat. The double-headed rail may be considered to have been introduced by Mr. Locke, who used it on the Grand Junction and the South Western lines in the form shown at *k*; and eventually, notwithstanding the other modifications of the rail with intermediate supports as at *m*, Mr. Locke's form has been generally adopted. At *g*, *n*, and *o*, are represented the manners of forming the end joints of the rails, either with a half lap, or with butt ends, the system now prevalent; and at *l* is shown a rail of a peculiar section designed to fit more closely to the tires of the wheel. At the present day, however, little attention is paid to this theoretical perfection of the roadway, and the upper and lower surfaces of the rails are made identically the same. When firstly the double-headed rails were introduced they were made in 15 or 16 feet lengths, of about 56 lbs. weight per yard forward; at the present day they are made of from 70 to 80 lbs. per yard, and are often of 21 feet length. The cast-iron chairs have also been increased in weight, and instead of weighing for the joint chairs 20 lbs., and for the middle 15 lbs. each, they now weigh for the joint chairs 38 lbs., and for the middles 21¼ lbs. each. Latterly when the rails have been fish-jointed, or made with fish plates weighing about 28 lbs. per pair bolted on the respective sides of the rail, the middle chairs only are employed, and the sleepers at the end of each rail are brought as closely to the fish joint as possible.

Fig. 11.



When Mr. Brunel attempted to introduce the broad gauge he also attempted to introduce the American system of placing the rail with a continuous bearing, and thus was led to adopt the form of rails represented by *p*, *q*, *r*, and *s* on *fig.* 12, partly with the hope of being able to diminish the weight of iron. He began to use rails weighing about 45 to 47 lbs. per yard, and they were bolted or spoked to the longitudinal baulks at distances of about 18 inches; but the continually increasing weight of the locomotives, and the increased rate of travelling, have forced the parties who have used the bridge rail to follow the example of the advocates of the double-headed one; so that at the present day the bridge rails are often made of even 90 lbs. weight per yard forward. The great objection to their use lies, however, in the necessity they involve for a very expensive timber substructure, which is liable to rapid decay, and to frequent deformations by the warping of the wood, or by the expansion of the rails. Practically, then, although the system of continuous bearings produces a road of a very pleasant description for the traveller, so long at least as it is in order, it is found to be of so costly a maintenance that it is rarely used in England, unless when the roadway has to be carried over viaducts, bridges, or other works, where the percussion upon the intermediate bearings might become injurious.

Fig. 12.



It may be as well here to observe, that in laying rails, the allowance for the elongation produced by summer heat must be very carefully made. In a 15 feet rail, the difference of length for an increase of 76° Fahr. will be about $\frac{1}{11}$th of an inch; but at the same time that provision must be made for the free expansion of the rails, they must not be laid with so open a joint as to give rise to concussions. It is usual, also, to give a slight inclination to the upper surface of the rails, inclining inward about 1 in 30, for the purpose of giving a better bearing to the conical surfaces of the wheels; and in curves, the outer rail is elevated above the inner one, by a height regulated by the maximum velocity attained upon the curve, and by its radius. Upon level crossings, very sharp curves, viaducts, or bridges, it is usual to fasten counter-rails; but they have so often proved sources of danger, through their independent movements, that these counter-rails are never placed unless under very exceptional circumstances. On level crossings they are necessary in order to protect the rails from the shocks of passing waggons. A very common elevation of the outer rails, on curves of 1000 yards radius (and this seems to be the minimum radius which should be allowed in railways upon which ordinary express speeds are attained) is about 2 inches; and in curves near stations, of 500 yards radius, the elevation becomes about 2¼ inches. Fractures of the rails occur on changes of temperature, and chairs are frequently broken when wedged up too tightly. Great care is therefore required in the inspection of the rails at these seasons; and it is worthy of remark, that there is a marked tendency of the rails to displace themselves in the direction of the movement of the trains, especially on inclines and near the stations. In some cases, every 10th or 20th rail is notched upon its chairs, in order to resist the tendency to this kind of displacement.

The battle of the gauges, which raged so furiously a few years since, has now been practically solved by the adoption of the mixed gauge on the Great Western line itself; and indeed the advantages of a uniformity of gauge are so much greater than those which can be secured even by a more logical arrangement than the one adopted originally by Mr. Stephenson, that it is almost idle to discuss the question at present. For all useful purposes, it is ascertained that the 4 feet 8½ inches gauge is as efficient as the 6 or 7 feet gauge; and it is immeasurably cheaper, both as regards the formation of the roadway and the construction of the rolling plant. It seems that the precise gauge of 4 feet 8½ inches was the result of a mere accident; but as it has been adopted on the majority of railways, it is now desirable to carry it out on all similar works. The space between the rails is usually made 6 feet from edge to edge.

Accessories of the Roadway.—It is often necessary to pass engines and carriages from one line of rails to another, and this is effected by means of switches or points, and crossings by turn-tables, or by traversing platforms. If we suppose, as in *fig.* 13, a series of cases in which such changes of direction may be necessary, we may perceive that some contrivance is required to guide the flanges of the wheels in such wise as to cause them to follow the new line of rail they are intended to travel upon. This contrivance consists of two moveable rails (*fig.* 14) working simultaneously and parallelly upon fixed pivots, so that the flange of the wheel on one side should bear against one of the rails, and should thus be forced to follow it, whilst the other flange would find an open passage which would allow it to follow the new line of direction given. Many varieties of points and crossings have been introduced from time to time, of which the most concise account is to be found in Perdonnet's 'Traité Elémentaire'; but for our present purposes it may suffice to say that the system now generally adopted is the one known by the name of Wyld's patent, in which the surfaces of the rails in the principal line are not touched, but the tongues of the points are made to pass gradually under the heads of the main rails. On the Great Western line many of the points were originally made as in *fig.* 15. The radius of the curves of the best points and crossings is usually made equal to 1650 feet, and care is taken that counterpoises should be fixed, to keep the main line open; as far as possible, also, no points should be fixed so as to meet the advancing trains on the main line. At the points of turns out of single lines of railways, and at the junction points of embranchments, signal posts are invariably fixed for the purpose of indicating which line is open, and the radius of curvature is made as large as possible. On the Belgian lines, the embranchments are made near the stations, and sometimes the radius of the points does not exceed 1000 feet; but it is to be observed that these embranchments have no back curves like those of ordinary crossings. It may be as well to add, that where the two rails cross one another, grooves are cut to allow the flanges to pass, and guard-rails are placed to check any tendency of the rails to leave the road, as shown in *fig.* 13.

Fig. 13.

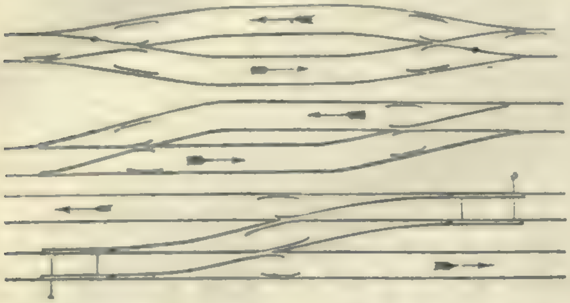


Fig. 14.

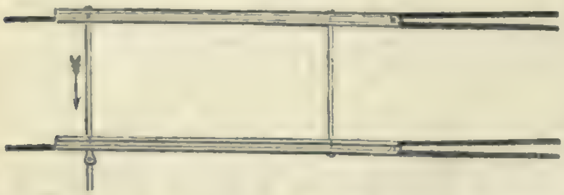

Fig. 15.

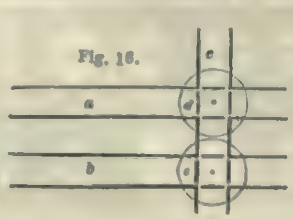
Turn-tables present a marked advantage over points and crossings in this respect, that they allow the carriages, &c., to pass from one line to the other in a much smaller space; but the operation itself is performed slowly, and must be repeated for every separate carriage. Turn-tables consist of circular platforms of wood and iron, fixed on a level with the rails, and mounted on friction-rollers, so as to turn freely upon their central pivots; four rails are fastened on the upper face, and made to correspond with the positions of the longitudinal and transverse rails at each quarter revolution, in such cases as those represented in *fig.* 16, wherein, if it were desired to transfer a carriage from the line *a* to the line *b*, the carriage would be rolled to *d*; a quarter revolution of the table is then made, and the carriage is pushed on to *e*; a similar quarter revolution of the table *e* is made, and the carriage could then be advanced in either direction on the line *d*. The dimensions of turn-tables depend on the sizes of the carriages to be moved: thus, for goods waggons, an 8-feet table will suffice; for passenger carriages a 12-feet table is necessary; whilst for locomotives and tenders coupled together, tables of as much as 36 or even 50 feet diameter have been made. Sometimes the turn-tables of stations are made to serve a series of converging rails; and in the engine-houses of some railways a large table is placed in the centre, so as to serve the purposes of as many as 16 lines.

Fig. 16.



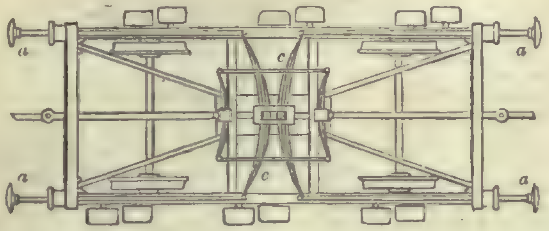
Traversing platforms are used when it is desired simply to pass engines or carriages from one line of rails to another situated parallelly to it. They are exclusively fixed in stations where no through traffic can possibly be admitted; because they consist of a platform susceptible of movement only in a direction transversal to that of the line of rails, and moving on rollers in a deep pit extending the whole length of the lines thus put in communication with one another.

Water-tanks, water-cranes, pumping-engines, and wells, constitute useful adjuncts of railways, but they hardly require special notice in this article. The signal posts, for both day and night services; the provisions for the establishment of the electric telegraph; the watch-boxes even for the guardians of the way in particular positions, must also occupy the serious attention of the railway engineer. Local circumstances must, however, so modify the manner of dealing with all these questions of detail, that it would be dangerous to attempt to lay down any absolute principles with respect to them, otherwise than by saying that every convenience should be provided to facilitate the discharge of duties upon which the safety of the public so materially depends. It may be added that, with respect to the service of the water-columns for the supply of tenders, the tendency of modern practice is to make them with reservoirs able to hold about 200 cubic feet of water, and to place those reservoirs immediately over the delivery-pipe, so as to ensure the rapid filling of the tenders; the reservoirs are themselves filled during the intervals of the trains. Heating apparatus are also provided for the water-columns, in order to prevent the freezing of the water. Good signals are especially required at the entrances of long tunnels, and at the points of the turn-outs of single lines of railway, or at embranchments.

On some lines, or portions of lines, as on the old Birmingham and the Blackwall Railways, upon the goods lines at Liverpool, and upon the line from Liège to the Prussian frontiers, it was thought advisable to substitute fixed machinery for the locomotives employed on the other parts of the line. These machines, in fact, gave motion to endless ropes, passing over grooved wheels and running from station to station upon friction-rollers, to which ropes the carriages were attached, and were thus hauled along. In almost every case, but those at Liège and at Liverpool, these engines have been abandoned; and indeed, the improvements lately introduced in the details of locomotive engines have rendered their intervention unnecessary; and it may be suspected that at Liège, even the fixed engines would have been abandoned, had they not been placed on a line in the direct control of the state. The same description of remark may also be extended to the atmospheric railway, which has been so universally abandoned by engineers, that it may suffice here to refer those who desire to make themselves acquainted with its practical and theoretical defects, to the late Mr. R. Stephenson's report upon the subject. The system thus referred to was tried on the largest scale, both in England and in France; and in both countries it has signally failed (when compared, economically) with locomotive traction. [ATMOSPHERIC RAILWAY.]

Rolling Stock.—Railway carriages for the conveyance of passengers are usually very capacious, the bodies being made to project over the wheels, which in ordinary lines are made 3 feet, or 3 feet 6 inches in diameter; but as the centre of gravity of the carriages is kept very low, the oversailing of the frame produces no evil effects. On account of the rapid speed at which the carriages travel, and the violent shocks to which they are occasionally exposed, their frames are necessarily made of great strength; and every precaution is taken by the introduction of springs and buffers to diminish the violence of the blows they receive, or the effect they themselves might produce upon the rails. Elasticity in the traction is also necessary as well for the safety and comfort of the passengers, as for the preservation of the carriages; and even in order to economise engine power, for if it did not exist, the engine would be obliged to exercise a greater power to start the trains than it would do for the maintenance of the speed once attained. Various contrivances, more or less successful, have been adopted to secure these conditions; but the system represented in *Fig.* 17, is the one usually adopted; it represents the plan of the framework of a carriage, the body being supposed to be removed. The frame is carried on springs fixed outside the wheels, and resting on brass bushes, which bear directly on the axles: *a*, *a*, *a*, *a*, are the buffers, or discs of wood or metal, covered with cushions, and fixed to the ends of metal rods, working between guides against the ends of very strong horizontal springs *c*, *c*. In such cases, when the train is suddenly stopped, the springs are forced against one another, and serve thus to soften the blow to an extent dependent upon the force of the spring. The draw-bars are also attached to the centre of the horizontal springs, and thus prevent any sudden jar to the frames of the carriages at their starting, and the several draw-bars of a train are attached to one another by a coupling chain, bearing a double thread, so as to force the buffers into close contact; loose chains are also placed by the sides of the buffers, in case the coupling chains should break. Many varieties of springs have been applied for both the purposes described above; but experience has led engineers to resort to the old-fashioned plate springs, of course of considerable thickness, and of the very best quality of steel. The ordinary first-class carriages have three compartments, able to contain from six to eight passengers in each compartment; the second-class carriages mostly have three or four compartments with ten passengers in each compartment; whilst the third-class carriages are made to contain from fifty to sixty passengers each. The weight of the best modern first-class carriages, on the narrow-gauge, is about 5¼ tons; that of the second-class is about 6¼ tons; and that of the third-class 6 tons: or, in other words, the ratios of the dead weights of the carriages to the loads transported are, in the several classes, as 2·9 to 1; as 2·1 to 1; and as 1·6 to 1. A certain number of the carriages in each train is made with breaks, and a guard's van, with occasionally an extra luggage van, are added. Horse-boxes, carriage-trucks, and post-office waggons are made upon the same principles of framing and suspension, as the ordinary traveller's carriages, so as to allow of their being added to the same trains as the latter. As the goods waggons do not travel at the same velocity as the waggons for the conveyance of passengers, there is not the same attention paid either to their modes of suspension, or to their draw-bars; but every waggon which is added to a train moved by a locomotive engine is hung upon springs, even when there is no spring draw-bar; there is very rarely any buffing apparatus attached to merchandise waggons. On ordinary narrow-gauge lines the weights of goods carriages range between 3 and 5 tons; they carry about 5 tons each.

Fig. 17.



As there is now almost a certainty that the broad gauge will be abandoned, it is only necessary to observe that upon that system the carriages are not only more expensive, but that the ratio of the dead to the useful weight is even more unfavourable than the one which prevails upon the narrow gauge lines. It may also here be added that upon almost all the continental lines of railway the carriages are much more commodious than they are upon the English lines; and that in America only two classes of carriages are admitted, one for the white passengers, the other for merchandise and negroes. The American carriages usually run on eight wheels, coupled by what are called bogie frames in two pairs, in order to diminish the length of the tangential line formed by the fixed axles with the curves of the roadway they travel over; the wheels, however, are very small.

We have already seen that, during the gradual development of the railway system, there has been a constant tendency on the part of machine-makers to increase the power and the weight of the locomotive engine, until it has at last attained the colossal dimensions before stated. Originally also the locomotives were made with only four wheels; but the frightful accident on the Versailles line in 1842 raised so strong a prejudice against engines of that class, that they have been universally abandoned. Six-wheeled engines are now the only ones used on our English railways; sometimes with the tenders attached to the engine, and upon the same frame; and sometimes with the tenders entirely detached, and carried upon a distinct set of four wheels, as is the case with any ordinary carriage. In America, and on the lines in Germany with very steep gradients, the engines are made with eight, or even with ten wheels; the tenders being, in either of those cases, upon the same frame as the engines, but the wheels working upon two bogie axle frames. In ordinary passenger engines the cylinders are placed internally, and the piston-head communicates motion directly to the crank upon the large centre wheels, which thus become the driving-wheels, leaving the fore and hind pairs of wheels simply to act as trailers. *Figs.* 18 and 19 will convey a tolerably correct notion of the engines thus referred to; and in them *a* represents the fire-box, usually made of copper, and surrounded by an outer casing of iron, so as to leave a space all round surrounded by water; *b* represents the boiler, with its horizontal tubes of about 140 or 150 in number, and made of brass, passing from the fire-box to the smoke-chamber, *c*; *d* represents the steam-chest, which in modern engines is made considerably smaller in proportion than it used to be. The steam passes through the smoke-box to the cylinders at *e*, and there is upon the tube which so conveys it a throttle valve, under the control of the driver; *f* and *g* represent the safety valves, and *i* the feed-pipes from the engine to the tender; *h* represents the steam-whistle. Until very lately all locomotive engines were heated with coke, but a notable economy has been obtained on some lines by the substitution of coal for coke, by means of some alterations in the fire-boxes and the grates. The escape-steam in all locomotives passes off through the chimney above the smoke-box. On some lines of railway the cylinders, instead of being placed inside the frame, are placed externally to it, so that the motion is communicated at once from the piston through the crank to the driving axle, without the necessity for forging a crank on the axle itself; but there seems to exist a great disinclination on the part of the majority of engine builders to adopt this simple arrangement, perhaps on account of the condensation which takes place in the cylinders, and on account of the frequent ruptures of the cylinders which occur in these engines. The driving-wheels of ordinary express locomotives, on Crampton's system, are now made 8 feet in diameter; the cylinders about 18 inches diameter, and 2 feet stroke; the heating surface in the fire-boxes is about 154 feet superficial, and the heating surface of the tubes about 2200 feet; the pressure of the steam is often 120 pounds on the square inch. Such an engine, with its tender filled with coke and water, would, at a maximum, weigh 36 tons; the trailing or carrying-wheels are 3 feet 6 inches in diameter.

Fig. 18.

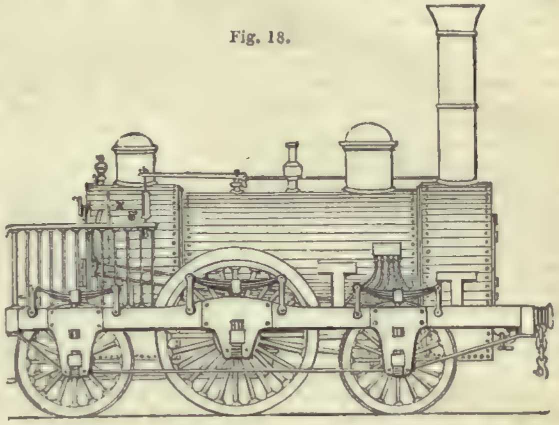


Fig. 19.

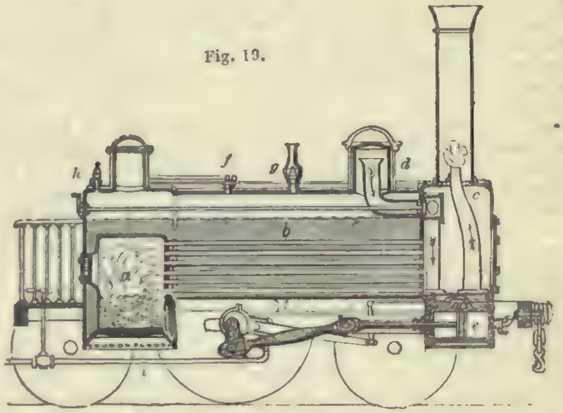

The goods engines are usually made with four driving-wheels coupled, of from 4 feet 6 inches to 5 feet in diameter, and two carrying wheels, for the narrow-gauge lines, at least, where the inclines do not exceed 1 in 100. On the line across the Sœmering, however, there are four driving-wheels coupled, and mounted on one bogie frame, and six carrying-wheels mounted on another. The object aimed at in these cases is to increase, as far as possible, the adhesion on the rails; and to secure the greatest possible length of boiler, and the greatest heating surface. The weight of an ordinary goods train may be considered to be about 150 to 250 tons; that of an ordinary passenger train about 60 to 100 tons.

Stations.—A very important part of the establishment of a railway consists in the erection of the intermediate and the end stations. The result of past experience seems to prove that it is by no means advisable to construct these buildings, at the first opening of a line, in a costly or a permanent manner; but rather that the true policy of a railway company is to purchase at once all the land that may be required, and only to erect the permanent buildings when the traffic has had time to develope itself. As a general rule, it would seem to be necessary to purchase an additional quantity of ground, beyond that which is required for the roadway, of about eight acres for a first-class intermediate station; and of about four acres for a second-class one; the terminal passenger station for a first-class railway will require an area of about 4 to 6 acres; whilst the goods station of such a line will require about 25 or 40 acres, and the repairing shops, carriage depôts, engine houses, coke ovens, may require at least 12 acres. It may be added that in a large passenger station at a terminus, as many as forty people are constantly employed; and in a large terminal goods station there are often as many as 140; on a first-class intermediate station there are usually about ten people employed, and on a second-class station only about four. It has been found that the average length of sidings for turn-outs and goods stations, on lines with a large traffic, is not less than from 12 to 15 per cent. of the whole length of the through way; and the expense of the station buildings has been found to be not less than 2000*l.* per mile lineal of the distance between the termini, when no very costly or monumental buildings have been attempted. In all cases the embarcation and landing of passengers should be effected under cover, and the same remark of course would apply to goods; the passenger platforms should be finished at the level of the floors of the carriages.

Cost.—Finally, it may be desirable to state that in England the average cost of all the railways already executed has exceeded 33,000*l.* per mile; but that there is little reason for calculating the cost of the railways which may have to be made hereafter at more than 16,000*l.* per mile, unless there should be an abnormal proportion of the line carried through town property. The rolling stock will be found to have cost from 2000*l.* to 3500*l.* per mile of railway; and of the portion of the capital specially devoted to the construction of the roadway, in double lines of road, the earthworks will cost about 40 per cent.; the permanent way 40 per cent.; bridges, &c., 12 per cent.; and land 8 per cent. Of course, however, these figures must only be regarded as rough average approximations. Every line of railway presents its own peculiar difficulties and special causes of expenditure. Thus it has arisen that the average cost of the railways in England has borne to those of other countries so very remarkable a proportion. With us they have cost nearly one-third more than in France; twice as much as in Belgium; two and a half times as much as in Germany; and about five times as much as in the United States of America.

Statistics of Railways.—It is difficult to collect any very trustworthy statistics of the precise state, at any particular moment, of a class of operations so essentially exposed to change as railways must be. The following table must therefore only be considered to represent the real state of the case in a very rude and approximate manner. Every month witnesses the opening of a new line of railway; every year witnesses the adoption of the railway system in a new country.

In the year 1856 it was calculated that railways had been commenced in Europe of the lengths subjoined. The population of the different countries is added. About three fifths of the length then undertaken had been completed.

Countries.	Population.	Miles of Railway.
Great Britain	27,323,000	12,801
France	35,547,000	7142
Germany, small states . .	16,804,000	2827
Austria	38,400,000	2701
Prussia	16,200,000	2557
Belgium	4,524,000	1118
Denmark	2,132,000	118
Spain	14,216,000	1339
Holland	3,242,000	208
Italy	17,000,000	1315
Russia	68,600,000	29

In Mr. Fenn's book, 'On the Funds,' he quotes (p. 400) from Mr. Danvers a table of perhaps greater interest than the one given above, insomuch as it contains much information as to the cost of some of the railways, and as to their commercial results, not only in Europe, but in other quarters of the globe.

Name of State.	Year.	Length of Line open.	Total Capital expended per mile of Line open.	Receipts from Traffic per mile of Line open.	Net Receipts per mile of Line open.	Proportion per cent. of Working Expenses to Receipts.	Proportion per cent. which Net Receipts bear to Capital expended.
		Miles.	£	£	£		
Austria . . .	1856	1586	16,378	2190	1040	52·70	6·32
Belgium	1856	445	16,391	2158	898	58·16	5·48
France . . .	1854	2913	25,668	2706	1515	44·01	6·58

In addition to these figures, it may be as well to state that, according to the Report on the Railways of Great Britain, issued by the Department of Railways in 1859, the total number of miles open for traffic was,

			£	s.	d.
In England and Wales .	7217 miles;	the receipts	9,989,959	17	6
In Scotland . . .	1369	,, ,,	1,267,792	3	9
In Ireland . . .	1210	,, ,,	604,987	9	8
Totals . . .	9796		£11,862,739	10	11

The total sum raised and expended on these lines to the end of December, 1859, was not less than 335,435,071*l.*

The returns given by Mr. Consul Ward of Leipsic show that in Germany Proper, in 1858, there were open for traffic 7360 miles of railway, which had cost about 120,000,000*l.*; and in addition thereto about 501 miles of railway had been opened in Hungary and Gallicia. The length of railway opened in the United States was, at the end of 1859, not less than 27,857 miles; they had been constructed at a cost of 192,209,473*l.*, and they yielded a total revenue of 9,681,500*l.* nearly. In Canada there were 2061 miles of railway opened up to the same period; and, in our East Indian colonies, 665 miles; whilst in the Cape colony, Ceylon, New Brunswick, Nova Scotia, Demerara, Jamaica, Australia; in the Brazils and the central American States, and in Cuba, numerous lines were opened, and in progress. The great company which is at work upon the main lines of Russia has undertaken to complete in ten years about 4162 miles of railroad; whilst in Asia Minor and in Egypt there are short lengths already open to traffic. In a very few years, indeed, railroads will be found in every civilised country, perhaps even to the exclusion of every other description of road; for in proportion to the value attached to time in commercial affairs will this rapid means of intercommunication become more and more necessary. The rates at which goods trains now move are between 17 and 20 miles an hour; the passenger stopping trains travel at rates of between 27 and 30 miles, and the express trains at rates of between 37 and 45 miles per hour. In these days, when time is emphatically money, no nation, which desires to maintain its position in the world, can dispense with a system which enables it to travel under the same conditions of speed as its neighbours, notwithstanding that the cost may be considerably greater in one case than in another. The Dutch government at last has felt this truth, and even it has been induced to commence a series of railways which will involve an outlay of at least 10,000,000*l.* sterling.

RAIN. The ancients appear to have been very imperfectly acquainted with the constitution of the atmosphere; and Descartes was probably the first who, in attempting to refer meteorological phenomena to their causes, approached near the hypotheses now generally received; for he ascribes the formation of clouds, snow, rain, and hail to variations of temperature in the upper regions of the air. He supposes that when the coldness of any portion of those regions becomes intense, the subtle matter disseminated among the particles of vapour becoming too weak to keep those particles at a distance from one another, the latter must rush together, and either form small spicular filaments or spherical drops of ice. The superficies of these filaments or drops being supposed to be considerable when compared with their volumes, he conceives that the resistance of the air may be great enough to prevent them from descending by their weight, and that thus a great assemblage of them may remain suspended in the form of a cloud above the earth. The filaments becoming by an accession of heat partially liquefied, it may happen that many of them will adhere together, and thus form flakes of snow, which, at length acquiring sufficient weight to overcome the resistance of the air, descend to the ground. In order to explain the origin of rain and hail, he supposes that the flakes, on arriving near the surface of the earth, may pass through a warmer region than that in which they were formed, and there dissolving, they assume the figure of spherical or spheroidal drops of water. Again, if in the descent the latter should meet a current of cold air, they become globules of ice. ('Meteora,' cap. v. vi.) The absence of observation in all this, however, is evinced by the theory of the formation of snow, to which it is evident that Descartes never applied even such a moderate magnifier as he might readily have obtained, or he could not have failed to see the true nature of its aggregation.

The diffusion of electricity through the earth and atmosphere has led some meteorologists to believe that the variations in its quantity or intensity in particular regions may be the cause of the formation of snow, rain, and hail. The electrical particles, being endowed with a great repulsive power, are supposed to keep in general the particles of vapour asunder; and when, from any cause, some given volume of air is deprived of its natural quantity of electricity, these particles unite by their mutual attractions, and thus form drops of rain or ice. From the showers which accompany a thunder-storm, there is no doubt that electricity co-operates in some measure in the production of rain; and it may be remarked in support of the above hypothesis that rain is most abundant among mountains, their elevated summits being favourable for receiving and discharging electricity; while in some regions where thunder is little known there is also little rain. But the idea that repulsive electrical particles keep asunder the particles of aqueous vapour is itself purely hypothetical.

The theory first proposed by Dr. Hutton of Edinburgh ('Trans. Roy. Soc. Edin.,' 1784), is that which appears to correspond most satisfactorily to the observed phenomena of the atmosphere; and accordingly it has been adopted by nearly every distinguished meteorologist since that time. This theory will be briefly described.

The atmosphere surrounding the earth is known to consist of air and aqueous gas or vapour, both of which are elastic; and, according to the experiments of M. Gay-Lussac, the elasticity of the vapour is equal to that of the air at an equal temperature, both when the vapour exists alone, and when it is diffused through the air; hence it is inferred that in the atmosphere the vapour and air are in mechanical mixture only, and also that the particles of the former have the power of moving freely in the intervals between those of the latter. The atmosphere is supplied with humidity by evaporation from the waters of the earth, and its power to hold the water in suspension depends on its temperature, an increase of the latter augmenting that power, and a decrease diminishing it: but in the theory of Hutton, the diminution of the power takes place in a higher ratio than the diminution of the temperature.

Now the quantity of moisture in the atmosphere will at all times be nearly equal to the greatest quantity that can be maintained in it in a state of vapour at the existing temperature. Therefore if two volumes of air thus saturated with moisture, but of different temperatures, become by any means mixed together, a mean degree of heat results from the union; but the whole quantity of moisture in the sum of the volumes of air will, agreeably to the theory, be greater than that which is due to the mean temperature, and the excess will of course be condensed or precipitated. The vapour so condensed forms a cloud [CLOUD]; and if this be specifically heavier than the air in which it is formed, it will begin to sink: the internal friction of the air, as Professor Stokes has recently shown, will for a time retard its descent, allowing it to remain suspended until the resistance from this cause is overcome by the increasing magnitude of the drops. Should the atmosphere near the earth be less dense than the cloud, the latter will continue to descend till it touches the ground, when the aqueous particles, if small, will form what is called a mist; or if large, and particularly if the condensation of the vapour has been rapid and copious, they will descend by their gravity in rain, snow, or hail, according to the temperature of the region in which they have been formed or through which they pass. It may happen, however, in the descent that a cloud arrives in a warmer region than that in which it was formed; in this case the condensed moisture may again become vapour, which may re-ascend to a region at which a new condensation takes place. But though it be true that some precipitation must follow, whatever be the difference between the temperatures of the two volumes of air, yet unless the mean of the two quantities of vapour should be greater than the quantity necessary for complete saturation at the mean of the two temperatures, the precipitation will not be perceptible in the form of rain.

In order to illustrate the general subject of clouds and rain, the late Professor Daniell, in his 'Essays on the Constitution of the Atmosphere' and 'Meteorology,' supposes, first, that the earth is a sphere of uniform temperature, and surrounded by an atmosphere of dry and permanently elastic fluid; and he shows that on this supposition the density of the air would diminish in a geometrical progression at elevations increasing by equal increments. He observes also that the temperature would decrease with the densities, and that the atmosphere would be constantly in equilibrio. This would continue to be the case if the general temperature of the sphere were to be increased, provided that increase were uniform at all points on its surface. Now, if the temperature of the sphere, instead of being uniform, were supposed to increase from the poles towards the equator, the unequal densities produced in vertical columns of the air by the differences of temperature at equal heights above the surface of the sphere, would give rise to lateral pressures which, in the lower strata, would produce currents tending from the poles towards the equator; but the elasticity of the air, which is constant near the surface of the sphere, varies with the height above that surface, according to such a law that, beyond a certain elevation, it would produce lateral pressures exceeding those which arise from the density in the neighbouring columns at equal altitudes, and thus there would arise a current in the upper regions flowing continually from the equator towards the poles.

He supposes next that the sphere is covered everywhere with water of equal temperature, and is surrounded by an atmosphere of pure aqueous vapour; and he shows not only that the density of this vapour would diminish upwards, according to the law before mentioned, but that the atmosphere would in this case also be in equilibrio and transparent even when the general temperature of the sphere experiences a uniform increase. But if the temperature of the sphere were to increase as before, from the poles towards the equator, the density and elasticity of the vapour varying also with the temperature, there would arise by evaporation at the equator a current tending from thence to the poles, and this, being condensed in its course, would return from the poles towards the equator in the form of water. The condensation thus going on would cause the atmosphere to be constantly charged with clouds and rain. Unless, however, the excess of temperature at the equator were maintained by some foreign power, as solar radiation, the temperature over the whole sphere would by degrees become equalised; the equatorial parts becoming cooled by evaporation, while the polar regions would become warmed by the condensation.

Mr. Daniell afterwards contemplates an atmosphere consisting of a permanently elastic fluid mixed with aqueous vapour, and surrounding a sphere of water of uniform temperature; and he observes that, since the evaporation would be slow, the small quantity of water precipitated would be almost immediately dissolved by the superior temperature of the stratum below, into which it would tend to fall; therefore this atmosphere would be free from clouds. But in the event of the temperature of the sphere increasing from the poles to the equator, the evaporation in the latter region would destroy the regular gradation of temperature in the atmosphere from the surface of the sphere upwards; the evaporated water rising to the middle regions would there, in consequence of the diminished temperature, give out its latent heat, and become condensed; then descending, it would acquire from below a new portion of heat, with which it would rise till it was again forced to part with its caloric. This process may be supposed to continue till those regions of the atmosphere become saturated with vapour, and at the same time rarefied by the heat. The rarefaction of the air would diminish its resistance to the general movement of the vapour towards the poles, and thus the vapour would rush with force in those directions; but on arriving in latitudes at which the temperature is too low to allow the air to hold it in solution, condensation would take place, and clouds would be formed.

The circumstances just mentioned correspond nearly to those which would take place about the earth if local and other accidental circumstances did not interfere with the general process. In its actual condition, when a column of air vertically over any place is from any cause heated more than the neighbouring columns, it begins to ascend by its diminished specific gravity, the colder air of the vicinity flows in to fill up the void, and thus the relation between the temperature and humidity at the place is deranged. Then, agreeably to the general theory of Dr. Hutton, a precipitation of the vapour takes place.

In proportion to the density of the vapour, the magnitudes of the condensed particles of water are greater (this, however, does not appear to be proved, and the magnitude of the particles must be in some ratio to the temperature of condensation); in the upper regions of the air the cloud assumes a light appearance, but below it is more dense. After their formation, the clouds are driven about by the winds, receiving new accessions of precipitated vapour till the air is no longer capable of supporting them, and then their substance descends in rain, snow, or hail.

On the supposition that the surface of the earth is without inequalities, and that the temperature gradually diminishes from the equator towards either pole, it should follow that the rarefaction of the air and the evaporation of the water, and consequently the quantity of rain, must diminish according to some law with the distances of places from the equator. Now the mean temperature in any latitude being known, the quantity of moisture in the atmospherical column at that latitude can be found, since it depends on the temperature: hence, knowing also the variations to which the temperature of the atmosphere at the place is subject in the course of the year, the mean annual depth of rain in that latitude may be computed. On such principles, Humboldt determined that the mean annual depth of rain should be, at the equator, 96 inches; in lat. 45°, 29 inches; and in lat. 60°, 17 inches. The circumstances, however, which render the temperatures in different latitudes, and even on the circumference of the same parallel, irregularities must produce irregularities in the quantities of rain which fall at different places; yet the results of observation show that, in proceeding from the equator towards the north pole, there is in reality a diminution in the mean annual quantities of rain.

From an average of the observations made during fourteen years (1810 to 1823 inclusive), the mean annual depth of rain on the Malabar coast is 123·5 inches, and the mean annual temperature is 80·4° (Fahr.), but the annual depths of rain are very irregular, and differ considerably. From a mean of observations for seven years (1817 to 1823 inclusive), the mean annual depth of rain at Bombay was only 85·24 inches. From a mean of observations during seventeen years (1802 to 1818 inclusive), Mr. Dalton makes the mean annual depth of rain at Manchester equal to 33·596 inches, the mean annual temperature being 47·6°; and here also the annual quantities of rain vary very irregularly. The same meteorologist estimates the average of the annual quantity of rain in England to be 31·3 inches; the greatest quantity, according to the data he investigated, being at Keswick in Cumberland (=67·5 inches), and the least at Upminster in Essex (=19·5); but it is supposed that this estimate of the mean quantity is higher than the truth, because too many of the observations were made in the maritime counties, where the atmosphere may be expected to be the most humid. According to observations made by members of the British Meteorological Society, collected and discussed by Mr. Glaisher, the quantity of rain that falls annually in the islands of Jersey and Guernsey is about 31 inches; in the counties of Cornwall and Devon from 30 to 40 inches, or in some places still more; in the Isle of Wight and over the south of England about 30 inches; about London 25 inches; about the town of Bedford and the cities of York and Durham 24 inches; near the east coast 27 inches; 30 inches near the west coast; and about 27 or 28 inches elsewhere.

The late J. F. Miller, F.R.S., of the Observatory, Whitehaven, Cumberland, by whom the meteorological phenomena of the English lake district were accurately observed and recorded, ('Phil. Trans.,' 1851, &c.) showed that in the valleys of Cumberland and Westmoreland, the usual fall of rain varies from 50 to 100 inches in depth in a year; and these large quantities increase with the elevation, till the greatest annual depth of rain is attained at the altitude of about 1000 feet; at higher elevations it decreases in amount. He records the very large fall of 38·9 inches in a single month, a quantity exceeding the average annual fall of all England. The hamlet of Seathwaite, in Borrowdale, was until lately considered to be the wettest spot in Great Britain, the rain-fall, in the year 1850, amounting to 143·96 inches. But Mr. Miller ascertained that this was greatly exceeded by a new station for observation about a mile and a-half south-west of Seathwaite, and 580 feet above it, or 980 feet above the sea-level, at the extreme southern termination of the valley, on the shoulder of Sprinkling Fell, or the Stye. In 1850 the rain-fall at this station amounted to 189·49 inches.

In regions where the trade-winds blow constantly rain seldom falls, and the reason may be, that both the temperature and the currents of air being there nearly uniform, the vapours raised from the ocean are carried about the earth without suffering those partial accumulations by which condensation and precipitation might be produced. But elsewhere the irregular distribution of land and water, the existence of mountain-chains, and even the various capacities of different parts of the earth's surface for absorbing or communicating heat, independently of variations in the electricity of the air, are to be considered as the most frequent causes of perturbation in the general currents of the atmosphere, and consequently of the fall of rain.

The dense mists which rest on the ocean near Newfoundland are precipitations caused by inequalities in the temperature of the ocean in the line of the *Gulf-stream*. In the year 1821, in consequence of very strong winds between the tropics during the summer having caused an extraordinary difference between the levels of the waters in the Gulf of Mexico and those of the Atlantic Ocean, the stream of warm water was found to extend eastward of the Azores; and it deserves to be remarked that this unusual circumstance was attended, both in France and in England, by a very hot and damp winter, together with an excessive fall of rain. (Sabine, 'Experiments on the Figure of the Earth,' 1825.) The rains which frequently deluge the tropical islands are in part produced by the volumes of air which are intermingled by the sea and land breezes; and those which fall at the time of the summer solstice in Africa may be ascribed to the immediate precipitation of the vapours which flow from the seas to supply the place of the rarefied air above the heated lands; while the drought which prevails in the sandy deserts of that quarter of the earth is partly explained by the level character of those deserts, over which the currents of air may be supposed to flow nearly without interruption.

From April to October, the winds blowing from the south-west towards the coast of Malabar are accompanied by heavy rains, and the circumstance may be accounted for by the vapours of the ocean being brought from a warm region to one which is less so, and consequently becoming there condensed and precipitated. On the other hand, the prevailing winds on the coast of Peru, being from the south and south-west, come from a cold to a warmer region; consequently a diminution of the degree of saturation must there take place, and the vapours remain uncondensed; accordingly it is found that rain seldom falls on that coast. The clouds which overhang the coast of Malabar during the monsoon above mentioned are arrested by the chain of the Ghauts, and while it rains on the western side the fair season is enjoyed on the coast of Coromandel. Again, the currents of air which pass over Peru, in crossing the chain of the Andes, where the temperature is lower, become condensed by the cold, and the rain is there precipitated in abundance. The vapours which come from the Atlantic Ocean, and pass over the south-western counties of England, must be more abundant than those which arrive there from the continent of Europe; and from observations made at Penzance, the rains which accompany the westerly winds at that place exceed those produced by the easterly winds in the ratio of about three to one.

In tropical regions, the quantities of rain which fall in different months of the same year are very unequal: at Bombay, the mean monthly depth in June was found to be 24 inches, and in October 1·26 inches. In temperate climates the quantities differ much less, but more rain falls during the second half-year than during the first.

In the article CLIMATE (vol. ii., col. 972) the local distribution of rain has been treated at some length, and the rainless regions of the earth particularly distinguished. An attribute of the latter, hitherto unnoticed, may now be pointed out: this is, the different condition of oxidisable and readily soluble substances in them from that characterising the same class of bodies in those countries which are ordinarily subject to rain, and in which, consequently, the earth, even in its depths, has been from time to time drenched with water during the present period of its physical history. Mr. Frederick Field, F.C.S., a chemist, who, during his residence for some years on the western side of South America, was actively engaged in the examination of its mineral products, remarks that, "In the northern part of Chili, where little or no rain falls, and the mines have only been recently worked, [and their contents, therefore, not long exposed to the action of the atmosphere,] many minerals in a highly oxidised state are found, which have been preserved untouched from the absence of any solvent. Arsenic is obtained sometimes as arsenious acid, and sulphur as sulphuric acid, in combination with the oxides of iron and copper. In Peru, even crystals of native sulphate of silver have been observed." ('Quart. Journ. of Chem. Soc.,' vol. xii., April, 1859.) In ordinary rainy countries, for the reason above stated, these substances are of rare occurrence, under occasionally favourable circumstances only.

In general the lowest stratum of air about the earth contains the greatest quantity of aqueous vapour; and hence it might be expected that more rain should fall on low level plains than in elevated countries. The contrary, however, is the fact: and this may be accounted for by the variety of currents among mountains, and by clouds resting frequently on the summits of hills without descending to the plains. While the average annual depth of rain at Keswick is 67·5 inches, in the interior of the country and on the sea-coast it is but 25 inches: and while the average depth on the St. Bernard is 63·13 inches, that at Paris is 20 inches only. Yet, from the observations of Dr. Heberden, Mr. Luke Howard, and M. Arago, it appears that the depth of rain on the level of the ground is greater than at the top of a building. The first of these philosophers found that the annual depth at the top of Westminster Abbey was 12·099 inches, while at a lower level, on the top of a house in the neighbourhood, it was 18·139 inches; and on the ground, in the garden of the house, it was 22·608 inches. M. Arago observed, from observations during twelve years, that on the terrace of the Observatory at Paris the annual depth was 50·471 centimetres (19·88 inches), while in the court of that building, which is 28 metres (30 yards) lower, the annual depth was 56·371 centimetres 22·21 inches).

On this subject we are now able to add some precise information derived from modern research. In 1833 was communicated to the British Association for the advancement of Science, a 'Report of Experiments on the Quantities of Rain Falling at different Elevations above the surface of the ground at York, undertaken at the request of the Association,'. by William Gray, jun., and John (now Professor) Phillips; to which remarks on their results were added by the latter; and the whole published in the 'Third Report' of the Association, pp. 401-412. These experiments were made at three stations; the summit of York Minster, at the height of 241 feet 10¼ inches above the river Ouse, which is nearly level with high water in the Humber; the roof of the Yorkshire Museum, at the height of 72 feet 8 inches, and at the distance of 1100 feet from the Minster; and in the Museum grounds, at the height of 29. feet, and distance of 136 feet from the Museum; the second and third stations were nearly equidistant from the Minster. These points embraced in a remarkable manner the desired conditions of gradation of altitude, openings of sky, and contiguity of position. The results for twelve months, exclusive of snow, were, in the order of altitudes, as follows:—15·715 inches, 20·182, 23·785. On these results Mr. Phillips remarks, after arranging them in relation to mean temperature and the season of the year, that the diminution of the quantity of rain received at different heights above the ground, as compared with that received on the ground, is very accurately represented by a simple formula involving one constant, namely, the square root of the height of the station above the ground, and one variable coefficient. He then examines Dr. Heberden's results at Westminster, noticed above, and finds that it is probable that they obey the same constant relation to height as those of York, but the values of its variable co-efficient are very different, a subject which he next proceeds to investigate, with reference also to Arago's observations at Paris. He finally obtains a remarkable and continued accordance between the co-efficient fixed by observation and those derived by two methods from a very simple view of the condition of the air as to heat and moisture, which appears to him decisive of the question as to the general cause of the variation of the quantity of diminution of rain at any one height above the ground. The observations strictly warrant the conclusion that the ratio of diminution at different heights is constant throughout the whole year. Professsor Phillips, therefore, offers the hypothesis, as a matter of very probable inference, "That the whole difference in the quantity of rain, at different heights above the surface of the neighbouring ground, is caused by the continual augmentation of each drop of rain from the commencement to the end of its descent, as it traverses successively the humid state of air at a temperature so much lower than that of the surrounding medium as to cause the deposition of moisture upon its surface. This hypothesis," he remarks, "takes account of the length of descent, because in passing through more air more moisture would be gathered; it agrees with the fact that the augmentation for given lengths of descent is greater in the most humid seasons of the year; it accounts to us for the greater absolute size of rain-drops in the hottest months and near the ground, as compared with those in the winter and on mountains; finally, it is almost an inevitable consequence from what is known of the gradation of temperature in the atmosphere, that some effect of this kind must necessarily take place."

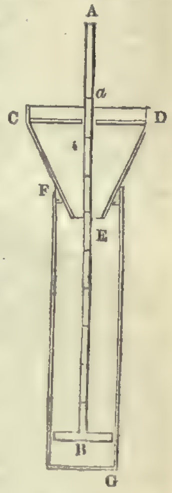
Mr. Howard has observed that, in this country, when the moon has south declination there falls but a moderate quantity of rain, and that the quantity increases till she has attained the greatest northern declination; and on some such results of observation the popular opinion that there is a connection between the alternations of rain and fair weather and the changes of the moon may be founded. The vexed question of the influence of the moon upon the weather appears to have received at length at least an approximative solution. Humboldt, in his 'Personal Narrative,' mentions as a phenomenon well-known to the pilots and seamen of Spanish America, the tendency to disappearance of clouds under the full moon. This meteorological fact has also been independently observed by Sir John F. W. Herschel, who was the first to recognise its importance in relation both to the radiation of heat from the moon and to the phenomena of the earth's atmosphere. The reviser of the present article has constantly observed, since Sir J. Herschel called attention to the subject, that when the full moon, or the moon so nearly full as to appear round, rises in a cloudy sky, she soon clears of cloud a circle of sky around her, which becomes larger and larger, often until the entire sky is freed of cloud. Referring to the induction of Arago, from a comparison of rain registered as having fallen during a long period, that a slight preponderance in respect of quantity falls near the new moon over that which falls near the full moon, Sir J. Herschel remarks, ('Outlines of Astronomy,' 5th edit., 432 and note), "This would be a natural and necessary consequence of a preponderance of a cloudless sky about the full, and forms, therefore, part and parcel of the same meteorological fact." [Hail; Meteorology; Mist; Snow.]

RAIN-GAUGE, a vessel for measuring the quantity of rain which falls on any particular part of the earth's surface, the quantity being indicated by the depth of the precipitated water which would cover the ground about the spot, supposing the ground to be horizontal and that the water could neither flow off nor penetrate into the soil.

In order to ascertain the quantity of rain which has fallen during the continuance of a shower, it might suffice to place a prismatical or cylindrical vessel, open at the top, in a horizontal position on the ground or on the top of a building, and, when the shower has ceased, to measure the depth of the water in the vessel by a scale of inches. But, unless the depth were ascertained immediately, a portion of the water would be carried off from such a vessel by evaporation, and the measure would be less than it ought to be. The difficulty also of ascertaining the true amount of a small depth of water would render the instrument of no practical use. For the purpose therefore of obtaining a more correct estimate of the quantity of rain, it has always been the practice to receive the water in a second vessel, or in a tube, the area of whose horizontal section is less than that of the first, so that the height of the column may be greater. And, since the heights of equal quantities of water in two prismatical or cylindrical vessels are inversely proportional to their bases, it is easy to perceive how a rod may be graduated so as to show, in inches, the depth of water in the upper vessel, and consequently the depth which would have lain on the ground if no absorption had taken place.

Originally this instrument, which has been called indifferently udometer (*ὕδωρ* and *μέτρον*), pluviometer (pluvia), and ombrometer (*ὄμβρος*, rain), was nothing more than a prismatical box, having a square base, open at the top and communicating with a prismatical box, placed vertically under it, by means of a pipe open at both ends; the area of a horizontal section of the lower box being, for the reason above given, less than that of the upper box. But it is evident that a prismatical or cylindrical vessel must retain, by adhesion to its sides and bottom, a sensible portion of the water which enters it; and consequently the depth measured in such vessel must indicate a quantity of rain less than that which has really fallen; it has therefore been customary of late to make the upper part of the vessel in the form of a funnel, or inverted cone.

The most general construction of a rain-gauge is shown in the subjoined diagram, which represents a vertical section of the instrument. The part CDE is a conical funnel, open both at top and bottom, and the lower extremity enters into the cylinder FG below, which thus receives the rain from the funnel. The rod AB passes through a perforation in a bar CD (in the direction of a diameter of the cone at its upper surface), and is attached, at B, to a circular piston, which has nearly the same diameter as the interior of the cylinder: the weight of the piston and rod is such as to allow the former to float with its upper surface on a level with the surface of the water; and the graduations, which are numbered towards B, commence from a point *a* on a level with the upper surface of the bar CD, when the piston B touches the bottom of the cylinder. A rim, of a cylindrical form, rises a little way above the upper extremity of the conical part of the funnel, in order to prevent the rain-water, which would strike the interior of the latter near that extremity, from being thrown out in consequence of the shock.



The diameter of the funnel at the top may be 12 inches, and that of the cylinder 6 inches; in which case the area of the horizontal section on which the rain falls will be to that of the cylinder in the ratio of four to one. Hence a depth of water equal to one inch at the horizontal section will be expressed by a space equal to four inches on the length of the rod; and, each of such spaces being divided into 100 parts, the depth of water at the said section will be indicated in hundredths of an inch. The height of the cylindrical vessel below the funnel may be from 25 to 30 inches.

For the sake of diminishing the evaporation and of measuring small quantities of rain with greater precision, the diameter of the cylinder is sometimes reduced to two inches, and the collected water is, by means of a small pipe, inserted in the bottom of the cylinder, and furnished with a cock made to pass into a glass tube whose interior diameter is half an inch. In this case, the diameter of the upper extremity of the funnel being the same as before, the area of the surface which receives the rain from the atmosphere will be to the area of a horizontal section of the glass tube as 576 to 1. Consequently a shower of rain whose depth on the ground might be one-hundredth part of an inch, would be indicated by 5·76 inches in the tube.

The funnel of the cylinder may be of tin or copper, and, however the instrument be constructed, it is evident that it should be placed in a vertical position in some place where no object may interfere with the free descent of the rain into the funnel. For the reasons stated in the previous article, the gauge should be placed as near the ground as possible, but the height should always be stated. At Greenwich there are several gauges, at different heights, and these record very different quantities of rain: for example, in 1846, the gauge 50 feet above the ground recorded 13·46 inches of rain; that at 24 feet, 22·63 inches; that at 2 feet, 25·86 inches. It is usual to observe the quantity of water in the vessel every morning, if rain has fallen during the preceding twenty-four hours; but, as some evaporation will take place, it would be advantageous to make the observations more frequently.

The sum of all the depths observed during any period of time, as a day, month, or year, will give the whole quantity of rain which has fallen in that time at the place. It is supposed that the rain falls uniformly over the tract of ground lying within the limits of the shower, and consequently that the quantity which passes through the circular area at the upper surface of the cone is equal to that which falls upon an equal area of ground anywhere within those limits. During windy weather rain may fall obliquely, so that a portion of it may not enter the gauge; hence, gauges have been formed with openings inclined to each of the four principal quarters, and these are said to register more rain than ordinary gauges. The *self-registering* rain-gauge is described under Anemometer.

A rain-gauge is a very imperfect instrument, and can never serve further than to give an approximation to the quantity of rain which may have fallen, since some of the water will always adhere to the sides of the vessel, but the following method of ascertaining the allowance to be made for the quantity thus lost has been recommended:—Let a sponge be made damp, yet so that no water can be squeezed from it, and with this collect all the water which adheres to the funnel and cylinder after as much as possible has been drawn off; then, if the sponge be squeezed, and the water from it be received in a vessel which admits of measuring its quantity, a near estimate may be made of the depth due to it; and this being added to the depth given by the instrument would probably show very correctly the required depth of rain.

The simplest form of rain-gauge is perhaps that by Professor Fleming. It consists of a cup or receiver, with the opening flush with the surface of the soil. The water is delivered by a funnel into a graduated jar below, which can be from time to time inspected. A small receiving vessel is preferred by some observers to a larger one. The area of the aperture must be accurately ascertained. The circular form is the best, since it admits of being turned in a lathe. The rim may be made to project, so as to retain the water which splashes up, especially in oblique showers. The divisions of the measuring jar should be tested by weighing the water. Some observers prefer to estimate the amount by weight, and an easy method of doing so is given in Drew's useful little volume entitled 'Practical Meteorology,' 1860.

RAINBOW, a circular arch of variously coloured light which is visible in the heavens when the sun or moon is shining, and when, at the same time, a shower of rain is falling on the opposite side of the spectator. When the rain is abundant, a second bow is commonly seen on the exterior, and concentric with the first; their common centre being in a line drawn from the luminary through the eye of the spectator and produced towards the opposite part of the heavens. Both bows consist of concentric bands of the different prismatic colours arranged as they appear in the solar spectrum, but the order in which they are disposed in the first bow is inverted in the second. The lower edge of the interior bow is violet and the upper edge is red; on the contrary, the lower edge of the exterior bow is red and the upper edge is violet.

The rainbow is a phenomenon which appears at all times to have been understood to depend upon the light of the sun or moon and the drops of falling rain; but the first complete explanation of the circumstances connected with it is due to Newton ('Optics,' book i., p. 2, prop. 9). In the beginning of the 16th century no better notion was entertained of the cause of the phenomenon than that the interior bow was a distorted reflection of the sun's image from the surface of a cloud, and that the exterior bow was a reflected image of the first. But the reflection of light is not capable of producing different colours, and it is said that Fleischer of Breslau (1571) was the first who entertained the idea that the particles of light from the sun entered into the drops of rain. His opinion was that a ray of light suffered one refraction on entering and another on leaving a drop; and that it entered the eye of the spectator after reflection from the surface of a second drop. It appears that Kepler, in a letter to Harriot (1606), suggested that the particles of light, in a ray which is a tangent to some part of the surface of a drop of rain, might enter the drop by refraction, and that this ray, being subsequently reflected at the interior surface of the latter, might enter the eye of the spectator after being again refracted on leaving the drop. The hypothesis is worthy of Kepler's sagacity; and, as far as it goes, it differs from the fact only in the manner in which the incident ray is supposed to fall on the drop. Newton ascribes the first idea of the true explanation to Antonio de Dominis, bishop of Spalatro, whose work, 'De Radiis visûs,' was published in 1611, but is said to have been composed in 1590: the work however appears to have been so obscurely written, and to betray so much ignorance of the laws of optics, that it is doubtful whether or not the author had any more than a vague conception of the cause of the colours. (See Montucla, 'Histoire des Math.,' tom. ii.)

Descartes is certainly the first who has distinctly explained the causes by which the two bows are produced, and he states ('Meteora,' cap. viii.) that he detected those causes on observing the phenomena presented by a glass globe filled with water, which he placed in various positions with respect to the sun. He shows that the interior or primary bow is produced by rays from the sun falling upon the drops of rain near their upper surfaces, where, being refracted, they pass to the side of the drop which is farthest from the sun and spectator; from thence they are reflected towards the lower surface, and, on quitting the drop, they suffer a second refraction. He shows also that the exterior or secondary bow is produced by rays from the sun falling upon the drops of rain near their lower surfaces, where, being refracted, they pass, as before, to the farther side of the drop; from thence they are reflected towards the upper surface, and there they suffer a second reflection. After this they pass to the side of the drop which is nearest to the sun, and from thence they emerge after a second refraction.

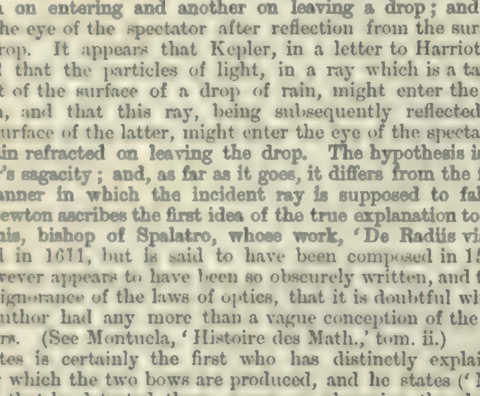


Fig. 1.

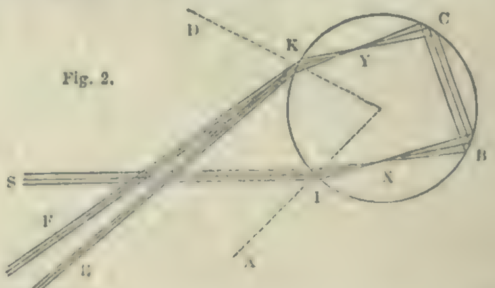
Now it is not sufficient that the pencils of light which are incident on the drops of rain should be so refracted and reflected; it is moreover necessary that each pencil on emerging from the drop should consist of parallel rays of light, that, when it enters the eye of the spectator, it may produce in the mind the perception of brightness; and Descartes determined by computation the positions of the incident and emergent rays so that this effect may be produced.

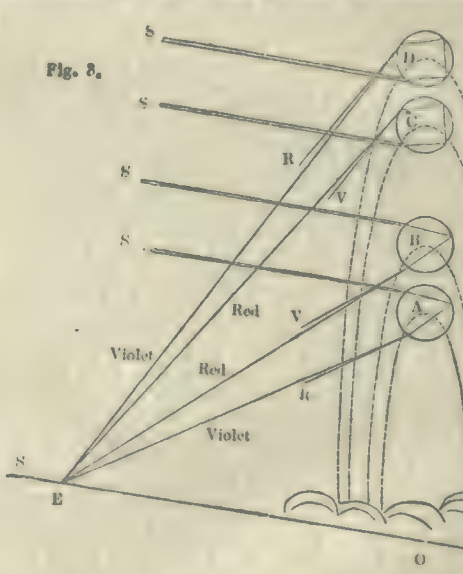
Thus, let S I (*fig.* 1) be a very slender pencil of rays of some one colour incident on a spherical drop of water at the angle A I S, and let this angle be such that the rays in the pencil may, by the laws of refraction in water, converge at B; then, though many rays will pass through the drop at that point and be dispersed, yet many will be reflected from thence as from a radiant point, and will emerge at K in parallel directions, as they entered at I, so that if K E be the direction of the emergent pencil, the angle C K E will be equal to A I S: the angle made by the lines S I and E K produced was found by Descartes to be about 42 degrees. If the angle A I S were varied, the rays of the pencil would leave the drop in a divergent state, and then the impression which they would make on the eye might be too feeble to produce the sensation of brightness. Again, let S I (*fig.* 2) be a very slender pencil of rays of some one colour incident on a spherical drop of water at the angle A I S, and let this angle be such that, by the laws of refraction in water, the rays, after crossing at X and being reflected from B, may pass from B to C in parallel directions; then, after a second reflection crossing at Y and being refracted at K, they will emerge in parallel directions as they entered at I, so that if K E be the direction of the emergent pencil, the angle D K E will be equal to A I S: the angle made by the lines S I and E K was found by Descartes to be about 52 degrees. If the angle A I S were varied, the rays of the pencil would leave the drop in a divergent state.

Fig. 2.



Now let A, B, C, D (*fig.* 3), be four globules of rain in a cloud covering a considerable part of the heavens on one side of the horizon. Let E be the eye of the spectator, and, on account of the remoteness of the sun, let the rays of light which proceed from his disc be considered as parallel to one another. Let S E be a line drawn from the sun through the eye of the spectator, and let it be produced towards O; also let S A, S B, &c., be very slender pencils of parallel rays (supposed at present to be of one colour) falling upon the globules of water. Let the refraction and reflection of these pencils in A and B be similar to those which are shown in *fig.* 1; and the refraction and reflection in C and D be similar to those in *fig.* 2; also from the points of emergence suppose lines to be drawn to E. It is evident, on account of the parallelism of the lines S O, S A, &c., that if the angle A E O or B E O were nearly equal to 42°,

Fig. 3.



and if the angles C E O or D E O were nearly equal to 52°, the eye would be affected by the sensation of brightness as explained above; therefore, if the lines A E, B E, &c., were to revolve conically about E O as an axis, all the globules of rain upon the conical surfaces so described would send pencils of parallal rays to the eye, and two concentric arches of bright light would be seen in the heavens. This hypothesis accounts satisfactorily for the existence of two concentric bows of bright light, but it affords no indication of the bands of colours of which they consist. Descartes, however, very sagaciously refers their cause to the decomposition of light on entering and quitting the drops of rain, observing that the convex surfaces of the drops must produce effects similar to those which take place when light is made to pass through the plane faces of a triangular prism of water.

But when Newton had discovered the different degrees of refrangibility in the different coloured rays which composed a pencil of white or compounded light, he was able to assign immediately the cause of the coloured bands in the rainbow, the order of their position, and the breadth which they must occupy. Thus, if the incident pencil S I (*figs.* 1 and 2) had consisted only of violet-coloured light (for example), the angle A I S must have had that particular value which alone would allow the rays of the emergent pencil to be parallel to one another; but if the incident pencil were supposed to consist of light of another colour, as red, it should have fallen a little further from the centre of the drop, in order that the angle A I S might have the particular value which would allow the rays of the emergent pencil to be parallel to one another. It may be proved without difficulty that the total deviation, when consecutive emergent rays of a given colour come out parallel to one another, is less for red rays than for violet; and if K E be the direction in which the latter emerge from a drop, K F in both figures may represent the direction in which the former would emerge, the variation of the course before emergence being omitted in the figures to avoid confusion; and if the eye were situated so as to receive the pencil K E, it would have the impression of a violet colour; while, if it were situated so as to receive the pencil K F, it would have that of a red colour. We have mentioned, for simplicity, only the violet and red rays, which form the two extremes of the coloured spectrum; but it is easy to conceive that a like explanation might be given for rays of the intermediate colours. And since the pencils of all the different colours diverge from one another on quitting a rain-drop, it is evident that the spectator whose eye receives one of the pencils will be affected by the colour of that pencil only, the other pencils passing either above or below his eye.

Newton has determined by computation that when the angle A E O (*fig.* 3) = 40° 17′, the violet rays alone, after two refractions and one reflection, will enter the eye of the spectator at E, the other rays falling below; and when ∠ B E O = 42° 2′, the red rays alone will enter the eye, the violet rays passing above. Again, when ∠ C E O = 50° 59′, the red rays only will enter the eye, after two refractions and two reflections, the violet rays falling below; and when ∠ D E O = 54° 9′, the violet rays alone will enter, the red passing above. If the interval between the drops A and B, and also between the drops C and D, were occupied by other drops, it may readily be imagined that the pencils of parallel rays which come from them to the eye would be of all the prismatic colours between the red and violet, and that thus there would appear in the heavens two narrow spectra: the length of that between A and B would be 1° 45′, and of that between C and D would be 3° 10′. Therefore, if all the lines drawn to E from the drops in the two spectra were to revolve conically about E O as an axis, the drops on these lines would be in situations to send to the eye rays of their own proper colours, and thus there would exist the appearance in the heavens of two concentric bands of variously coloured light.

But it has been here supposed that the pencils S A, S B, &c., come from the centre only of the sun's disc, whereas each point of the disc produces two bows similar to those which have been described: therefore the lower extremity of the interior bow will be a violet band whose breadth is equal to half the diameter of the sun (suppose 15′), and which is situated immediately below the violet line formed by the centre of the disc; and in like manner the upper extremity of the interior bow will be a red band whose breadth is also = 15′, and which is situated immediately above the red line formed by the centre of the disc: consequently the whole breadth of the interior bow is about = 2° 15′. Similarly 30′ (the measure of the sun's diameter) must be added to the breadth of the outer bow, as before determined, which thus becomes about = 3° 40′. In both bows, the colours between the violet and red are less distinct than those two colours, because of the mixture of the coloured light from all parts of the disc.

On account of the two reflections which take place in the interior of the drops which give rise to the outer bow, while there is but one reflection in those which produce the inner bow, there must be a greater quantity of light lost by transmission through the drops in the former case than in the latter; and hence the outer bow is always fainter than the other.

The effect of the light of any given colour which comes out of the drop in a divergent state has been neglected in the preceding investigation, but it is by no means insensible, especially in the neighbourhood of the bow, where the divergence is not great. If a ray which emerges after one or two internal reflections be first supposed to be incident along a line passing through the centre of the drop, and the line of incidence be then conceived to move parallel to itself until having passed through S I in *fig.* 1 or 2, it just grazes the surface, it will be found by calculation that the deviation, at first 180° or 360°, decreases until the position is reached in which consecutive rays come out parallel, after which it increases again. In *fig.* 1, the deviation takes place in the direction of the motion of the hands of a watch, and in *fig.* 2 in the contrary direction. Hence the rays which emerge with greater deviation than K E, are situated (as to their directions) *above* K E in *fig.* 1, and *below* K E in *fig.* 2; and therefore in *fig.* 3 the drops to which they refer would be situated *below* A or B in the former case, and *above* C or D in the latter. Hence, considering light of one colour only, and again regarding the sun as a mere point, we ought instead of two bright circles in the sky, in the positions determined above, to have two bows, in each of which the brightness terminates abruptly on the side towards the other, and fades off on the other side. Hence, considering the joint effect of all the colours, we see that they must be more mixed together, especially about the blue and violet, than would otherwise have been the case. In a vivid solar rainbow the darkness of the space between the bows compared with the space immediately within the primary bow is readily seen.

There is one part of the phenomenon which cannot be explained merely by geometrical optics, namely, the existence of what have been called *supernumerary bows.* In the upper part of the primary solar rainbow two or even three maxima of red may frequently be seen on the inside of the principal maximum, forming as many additional or supernumerary bows, decreasing in vividness and in breadth on receding from the principal bow inwards. Even the secondary bow, notwithstanding its comparative faintness, shows symptoms of the same phenomenon. The existence of these bows was first explained by Dr. Young, who pointed out that the light corresponding to any particular direction within the bow was double, and that the two portions were in a condition to interfere. The explanation, however, resulting from the application of the principle of interference to two systems of rays whose courses are determined by geometrical optics is imperfect, and would make the illumination increase to infinity on passing from the illuminated side to the place of the geometrical bow, and then ceases abruptly. Whenever such results follow from the calculations of geometrical optics, it is found that they are modified in practice by the phenomena of diffraction. The complete explanation of the supernumerary bows, according to the principles of the undulatory theory, has been given by Mr. Airy, in a paper 'On the Intensity of Light in the neighbourhood of a Caustic' ('Camb. Phil. Trans.,' vol. vii., p. 379), and his results have been verified by the observations of Professor Miller.

A rainbow can never be greater than a semicircle, if the spectator be not on elevated ground; for if it were, the centre of the bow would be above the horizon, and the sun, which is in a line drawn through that centre and the eye, would then be below the horizon; but, in this case, the sun could not shine on the drops of rain, and consequently there would be no bow. When the rain-cloud is of small extent, there is seen only that portion of the bow which the cloud can form; yet the bow is sometimes seen against the blue sky, which happens when the rain in falling is seen on a part of the sky which is free from cloud; and a portion of a bow is frequently seen in an inverted position on the ground by the refraction of the light in drops of rain adhering to the grass or the leaves of trees. It may be added that a coloured bow similar to that which is produced by rain may be observed in the spray from a waterfall, or from a fountain, when the jet of water is agitated by the wind, and also in the mists which at times lie upon low grounds.

The lunar rainbows appear in general in white; and when they are coloured, they differ from those produced by the sun only in the colours being much more faint. The faintness of the colour, or its entire absence, is accounted for by the fact that when light is excessively faint, all perception of colour is lost.

The circle of light which is occasionally seen surrounding the sun or moon at a considerable distance from the disc of the luminary is called a *halo,* and is caused by the refractions of light in particles of ice which float in the air. It must not be confounded with a *corona,* which consists in one or two coloured rings immediately surrounding the luminary, and is distinguished from a halo by the variability and comparative smallness of its diameter, and by the order of the colours,—red outside, blue inside—which is the reverse of the order in a halo. The corona is due to the globules of water constituting a thin veil of cloud, and is a phenomenon of interference, which may be imitated by viewing a candle seen against a dark background through a piece of glass dusted with lycopodium. The two halos most commonly seen have radii of about 22° and 46°. The phenomenon of halos having some resemblance to that which has been just described, a brief explanation of it may be with propriety introduced in this place.

The cause of the halo was first investigated by Des Cartes, who observes ('Meteors,' cap. ix.) that this phenomenon differs from the rainbow, inasmuch as the latter is seen only while rain is falling, whereas halos are never seen at such times; and he ascribes their formation to refractions of light in star-shaped crystals of ice, which he remarks are thicker in the middle than at the edges, and are therefore proper to produce refractions.

Sir Isaac Newton also ascribes the halo to refraction in floating hail or snow; but it appears that Mariotte (in 1686) was the first who considered it to be produced by refraction in the small equilateral prisms of ice which abound in the air in a separate state before they unite together and form the flakes which descend during severe frosts; and Dr. Young, without being aware of Mariotte's hypothesis, entertained and developed the same idea.

According to this philosopher, there may be in the air an immense number of prismatic particles whose transverse sections are equilateral triangles, or equiangular hexagons, the planes of the sections deviating but little from one passing through the sun or moon and the spectator. Now by the laws of refraction in water, when a pencil consisting of parallel rays of light, as S I (*fig.* 4) is incident on a face of such prisms and makes the angle of incidence S I P equal to about 41° 50,′ the axis K E of the emergent pencil will make an equal angle E K Q on the other face, and the angle of deviation S A F, or the angle between the incident and emergent ray, will be 23° 40′. Therefore if the line F E produced to the spectator's eye were to revolve conically about a line joining the sun and spectator as an axis (which line, since the sun is very remote, may be considered as parallel to S A), all the prisms similarly situated on such conical surface would transmit to the eye pencils of parallel rays, if the light were of one colour, and thus there would be produced the perception of a bright circle in the heavens, having the sun for its centre; its radius subtending at the eye an angle of about 23° 40′. The angle S A F varies very slowly, the variation amounting only to about 3°, when the angle S I P varies as much as 30°, consequently there may be innumerable prisms in the air in such positions that the angle S I P, for pencils incident upon them, does not vary more than 15° on either side of that which has been above supposed; and these will transmit to the eye light in such abundance as to produce the appearance of an annulus about 3° broad. This is the appearance of the common halo, the slight excess of the calculated radius over that observed being accounted for by the fact that water is a little more refractive than ice.

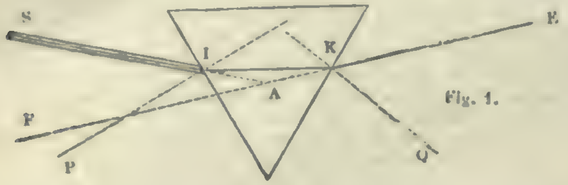


Fig. 1.

The larger halo is accounted for in a similar manner, by refraction through ice prisms of 90°, this angle being contained between the plane ends and side faces of hexagonal prisms of ice. The radius, calculated with 1·310 for the refractive index of ice, is about 45° 46′, which agrees very well with the angle observed.

The horizontal parhelia which are seen at the same altitude as the sun, a little outside the smaller halo, are accounted for by refraction through prisms of ice of 60°, which, instead of being placed on the average alike in all directions, have their axes vertical, in consequence of the resistance of the air as they fall under the influence of gravity. As the incident and emergent rays make with the axis of the prism an angle equal to the zenith distance of the sun, the minimum deviation is greater than what corresponds to refraction in a plane perpendicular to the axis of the prism, which accounts for the parhelia being situated a little outside the halo. This is the commonest example of that curious class of halo phenomena, where the appearance is no longer the same (except as to interruptions in the icy clouds) all round the line joining the eye and the sun, but has reference to the vertical. The reader who desires further information on this point is referred to an elaborate memoir by M. Bravais in the 31st *cahier* of the 'Journal de l'École Polytechnique,' where the subject is almost exhausted.

RAISINS. The dried fruits of several varieties of the vine are called raisins, a term derived from the French: raisin in that language being a general name for grapes, the dried fruit being distinguished as *Raisins secs ou passés.*

Raisins are named after the countries where they are produced, or the places whence they are imported; as Malaga, Valencia, and Smyrna. The peculiar small and generally seedless grapes, formerly called *Corinths,* are now better known as the dried or Zante *currants* of the shops. Other denominations by which different kinds of raisins are distinguished, arise from the variety of grape employed, or from the mode of preparation; as muscatels, blooms, sultanas, raisins of the sun, and lexias.

The most simple, and, when circumstances are favourable, the best mode of preparation, is to dry the grapes, after being cut when fully ripe, by exposure to the heat of the sun on a floor of hard earth or of stone. Another method is to cut the stalk half-way through when the grapes are nearly ripe, and leave them suspended till the watery part is evaporated; the flow of sap is in a great measure prevented from entering the fruit, in consequence of the incision, and whilst evaporation continues to go on undiminished, desiccation must take place. Some sorts are prepared by dipping the grapes in a ley, and afterwards drying them in the sun. This ley is formed of water, wood-ashes, and a small portion of olive oil. The ashes of vine branches and tendrils are preferred. In Valencia, in addition to the ashes of rosemary and vine branches, a little slaked lime is used. Raisins so prepared are called lexias; whilst those prepared entirely by sun heat are denominated raisins of the sun A fourth method, only used for raisins of inferior quality, is to dry the grapes in an oven.

The *currant*-grapes are gathered in the end of August and beginning of September. Rains often spoil the crop when they occur at the time of gathering or drying. The fruit, when sufficiently dry, is separated from the stalks by small rakes, and afterwards stored in magazines, *seraglie,* constructed somewhat like a lime-kiln, having an opening at top, where the fruit is put in, and a door at bottom, opened only at the time of sale. The fruit is rendered so compact by its own weight, that considerable force is requisite to break it up for the purpose of being packed in the large casks in which it is exported.

Of all the known varieties of grapes, the white muscat of Alexandria is that which furnishes raisins of the finest description. The berries are large, oval, white, rather firm-fleshed, with a rich muscat flavour.

From the synonyms which it has obtained, its extensive cultivation and use as a raisin grape may be inferred; for example, it is called the muscat of Jerusalem, Malaga, Passé-Musquée, Passé-Longue Musquée, Muscat d'Espagne, &c. There is also a black muscat of Alexandria, and a red muscatel, both of which have a firmness of pulp which renders them fit for drying; for grapes, however rich they may be, and excellent in a fresh state, yet if they do not possess a certain degree of firmness, are unfit for drying, inasmuch as their substance would be too much dissipated in the process.

The variety of grape-vine that bears the small and generally seedless bunches of grapes, which, when dried, become the *Corinths* or *Zante currants* of the shops, belongs to *vitis vinifera.* The berries of those grown in this country have the same size and character as those imported, being small and seedless, except occasionally one that acquires a somewhat larger size and contains a seed; such are even found amongst imported fruit. The first grapes of this variety that appeared in the great marts of Europe were brought at the beginning of the 17th century from the Gulf of Corinth, and hence were called *Corinthian* raisins. Latterly however the cultivation has become chiefly confined to the western territories of the Morea and the Ionian Islands, particularly those of Zante, Cephalonia, and Ithaca. The fertile island of Zante is the place where this variety of grape is produced in greatest abundance.

Nearly all the raisins imported into this country come from Spain and Turkey. A small supply is received from Portugal, Italy, and the Cape of Good Hope. Malaga and Valencia are the two great Spanish ports of shipment. Nearly the whole of the supply from Turkey is shipped at Chesmé and Vourla, small ports near Smyrna, the only raisins shipped at Smyrna being the small fine species called sultanas. Chesmé owes its prosperity entirely to this trade; and the Franks go down there in the month of October merely to ship the fruit which is produced in great abundance in the vicinity.

Raisins are imported in drums of 24 lb. each, in boxes of 22 lb. and 56 lb., and in casks of 1 cwt. and 2½ cwt. The import duty was fixed in 1860 at 7*s.* per cwt. In 1859 the imports were 558,000 cwt. of currants, and 429,000 cwt. of raisins. A small per centage of the imports, however, is re-exported, with a drawback of duty.

RAJA is a Sanscrit word, signifying king or ruler, and is the same word as the Latin *rex, reg-is.* In the ancient writings of the Hindus the word is applied to all the different kings or princes of Hindustan, and the title is still given to native princes.

RAMA. [VISHNU.]

RAMADHA'N, the ninth month in the Arabian calendar, and a sort of Lent observed by the Mohammedans, in obedience to the express command of the Koran. During this month every good Moslem is bound to fast from the first appearance of day-break until sunset. He must abstain from eating, drinking, smoking, smelling perfumes, and all other unnecessary indulgences or pleasures of a worldly nature; even from intentionally swallowing his spittle. He is allowed to bathe himself, but it is on condition that he is not to plunge his head under water, lest some drops should enter his mouth or ears. Some even are so scrupulous that they will not open their mouths to speak, for fear of breathing the air too freely. To make amends for this extreme rigour, Moslems generally feast all night till day-break, though the more rigid begin the fast again at midnight. As the Ramadhán happens at different seasons of the year, the fast is very severe when it falls in summer; the abstinence from drinking being most painfully felt. Persons who are sick, or on a journey, and soldiers in time of war, are not obliged to observe the fast during this month, but then they should fast an equal number of days at a future time. Fasting is also dispensed with in the case of nurses and pregnant women. The prophet even disapproved of any persons keeping the fast of Ramadhán, if not perfectly able; and he desired no man to observe it so strictly as to injure his health or disqualify himself for necessary labour, which is frequently the case among the lower classes of people. The reason given by the Mohammedan theologians for the month of Ramadhán having been fixed upon for this purpose is, that the prophet received his first revelation in that month; others pretend that it was chosen by Mohammed from its being generally spent by the ancient Arabs in revelry and mirth and excessive drinking.

RAMPART, probably from Ripa, an embankment, from which is derived the Italian word "Riparo," and the French word "Rempart," is, in modern fortification, a mass of earth often nearly 80 feet thick, surrounding a town or a military position, or constituting the faces of an outwork, and supporting the parapet; and its use is to protect the interior of the place or work against any sudden enterprise of the enemy, as well as by raising the parapet to give the defenders a superiority of elevation with respect to the works of the besiegers.

The ramparts of ancient fortresses were walls of stone or brick, frequently from 60 to 100 feet high and 20 feet broad, including the galleries made in them: round or angular towers were formed at intervals along the walls; and, by means of the galleries, the defenders could pass within the thickness of the wall from tower to tower. The rampart was surmounted by a parapet seven feet high and two feet thick, which was provided with battlements; the rampart was loop-holed, and, in order that the exterior foot of the high wall might be defended, machicolations were formed at the top, particularly over the entrances. [BASTION.] A great mass of earth was raised against the interior side of the walls, nearly as high as the top, in places where elevated ground or the enemy's works on the exterior allowed access to the top of the wall to be gained in force: and on this mass the cohorts were drawn up in order of battle. (Vitruvius, lib. i., cap. v.)

The modern rampart is surmounted by a parapet of earth, on the interior side of which, towards the town, is a nearly level space, varying in breadth from 35 to 40 feet, called the terreplein of the rampart; on this terreplein the artillery is placed: and in the rear of the guns there is room for the movements of the defenders and the conveyance of the ammunition. The exterior and interior sides of the rampart are formed with slopes making angles of about 45 degrees with the horizon: or they are retained by revetments, or walls of brick or stone, nearly upright, the exterior face of the rampart constituting the *escarp* of the ditch in front. The rampart immediately surrounding a place is divided, in the direction of its length, into parts making salient or re-entering angles with one another; and these parts constitute the faces and flanks of the bastions, and the curtains which connect the latter together. Not more than 30 feet are allowed for the breadth of the terrepleins of the ramparts of outworks, measured from the foot of the parapets, in order that the enemy may not be able to form batteries for artillery upon these terrepleins. The terrepleins of all ramparts should have a small slope down, towards the interior, in order that the rain-water may not lodge on them, and that the defenders near the interior edge of the rampart may be effectually covered by the parapet. The terreplein and the interior slope of a rampart, as well as the surface of the parapet, are generally covered with turf. A rampart whose exterior side is of earth, or without a revetment of brick or stone, might be easily ascended by an enemy at the time of an assault; and the palisades or fraizes which, in that case, would be planted in it for the purpose of impeding the progress of the enemy, might be easily destroyed by artillery, so that the place would be liable to be carried by a sudden assault. It is usual therefore always to have a revetment either supporting the earth or *detached* (see REVETMENT), except in cases where a *coup-de-main* is rendered impossible by wet ditches.

The relief, or height, of a rampart is regulated by the occasional necessity of employing a fire of artillery from the rampart, and, at the same time, a fire of musketry made over the glacis by men stationed in the covered way beyond the ditch in front of the rampart: for this purpose a line of fire from the rampart should pass three or four feet above the crest of the glacis in its front, in order that the wind of the shot may not injure the defenders. The relief of a rampart with its parapet may, therefore, be thus determined:—On a drawing representing a vertical section of the works let a line be drawn from the foot of the glacis, through a point taken at 3 or 4 feet above the crest of that work, and let it be produced till it cuts the interior slope of the parapet on the rampart: this intersection will give a point in the axis of a gun placed on the rampart, or a point a few inches above the sole of the embrasure, that is, about 3½ feet above the terreplein of the rampart; and, because the artillery and the gunners are to be protected by the parapet, if 7½ or 8 feet be added to the height of the terreplein of the rampart, above the ground, the sum will be the required height of the crest of the parapet.

RANGE. [GUNNERY; PROJECTILES.]

RANGER (*Rangeator*), an ancient officer in the king's forests and parks, appointed by patent, and enjoying certain fees, perquisites, and other advantages. His duty was of three kinds: 1, to make daily perambulations, to see, hear, and inquire concerning any wrong doings in the limits of his bailiwick; 2, to recover any of the beasts which had strayed beyond the limits of the forest or chase; and, 3, to present all transgressions at the next forest-court.

RANSOM, a word common to the French (rançon) and English languages, the sense of which is a sum of money paid for the redemption of a captive.

The paying of ransoms is an event of frequent occurrence in the middle-age history, and indeed may be traced in the history of the older nations. Nothing appears on the first view more reasonable, or would more naturally arise out of the relations of two parties in a state of hostility, than that compensation of some kind should be made for the restoration of prisoners, which compensation was most easily estimated and discharged by means of the common medium of exchange. In modern warfare we hear little of ransoms. It rarely happens that a person is taken captive whom it is of importance to redeem; and when prisoners are to be redeemed, it is usually done by way of exchange, and those who remain over, at the conclusion of a war, are usually delivered up as a part of the concession of the party in whose favour the difference is found to be.

In the indentures of military service in the middle-age period, as in the wars of Henry V., for instance, it was a usual stipulation that, while the ransom of persons of inferior condition taken in the war was allowed to those by whom they were captured, the ransom for persons of rank was to belong to the king.

The ransoms demanded for persons of eminence were often very large sums of money; so much beyond the power of any family, however great, to command by the ordinary resources, that the persons who held lands of them were called upon to contribute in proportion to the extent of land held. It was one of the three casual occasions of expense when this kind of extraordinary aid was demanded as of prescriptive right by the sovereign, as in the case of Richard I. of England, of David Bruce of Scotland, and of John of France; the other two being on occasion of knighting the eldest son, and of marrying the eldest daughter.

RANULA is a tumour formed beneath the tongue, and probably resulting from an obstruction of one or more of the ducts of the sublingual salivary glands. The tumour is usually of a rounded form, with a smooth polished surface similar to that of the adjacent mucous membrane. When small, such a tumour produces so little inconvenience, that it is usually not discovered till it has existed for some time. As they increase in size however, these growths, though seldom attended with pain, produce great inconvenience, by obstructing all the movements of the tongue. They usually burst when they have attained the size of a walnut, but they sometimes continue to increase beyond this size, and have been seen large enough to contain a pint of fluid. Their most usual contents are a transparent yellowish viscid fluid, resembling in consistence the white of an egg; sometimes, however, the material within them is much thicker, and sometimes mixed with portions of earthy matter, similar to the larger masses by which the salivary ducts are occasionally blocked up.

The treatment of Ranula consists in making a free incision into the front of the tumour, so as to let out all its contents. Means must then be adopted to prevent the edges of the wound from uniting again; and the best plan for this purpose is to rub the surface of the cyst with nitrate of silver (lunar caustic). If the wound be not prevented from uniting, the tumour will form again, and the same proceedings must again be adopted for its cure.

RANZ DES VACHES ('Kuhreihen' in German) is the name of certain simple melodies which are great favourites with the mountaineers of the Alps of Switzerland, and which are commonly played upon a kind of long trumpet called the Alp-horn. The sounds of these tunes, as well as the words which are set to them, are expressive of the scenes and business of pastoral life; the hut, the roaring torrent, the bellowing of the cattle, and the tinkling of the bells which are suspended from their necks; and the associations which they thus recall to the minds of the natives when they are in foreign countries, often produce that unconquerable longing for home which is said to have been especially remarked among the Swiss soldiers on foreign service; for this reason, the bands of the Swiss regiments in foreign service were forbidden to play the Ranz des Vaches. Theodore Zwinger, of Basel, wrote, in 1710, a 'Dissertation on Nostalgia,' in which he gave the music of the Kuhreihen of Appenzell, which is one of the oldest, and which was introduced into England in the time of Queen Anne, who had it often played by her band. The words begin thus: "Wänder yha, wänder yha, wänder yha, Lo . . . . ba." Each of the various pastoral districts, the Oberland, the Emmenthal, the Entlibuch, the Appenzell, the Gruyère, has its Kuhreihen. The western or Romand districts of Switzerland have their Ranz des Vaches in their respective patois or dialects.

A collection of the various Ranz des Vaches and other Swiss airs has been published: *Sammlung von Schweizer Kuhreihen und Volksliedern*, Bern, 1818; and they are included in the *Allgemeine Schweizer Liederbuch*, published in 1851.

RAPE is the having unlawful carnal knowledge of a woman against her will, and is a capital felony. A person under fourteen years of age is in law presumed to be incapable of perpetrating this offence: this presumption however is based on physical grounds entirely, so that such a person, by assisting others of maturer age, may render himself liable to the full penalty of the law as a principal in the second degree. In the case of a female under ten years of age, whether the act takes place with or without her consent, it is equally punishable as rape; if she be above ten and under twelve years of age, her consent reduces the act to a misdemeanor punishable by imprisonment and hard labour for such term as may be awarded.

An assault with intent to commit a rape is a misdemeanor punishable by imprisonment for any term not exceeding two years, and with or without hard labour, at the discretion of the court before which the offender is convicted. Upon a trial for the capital offence, where the evidence is incomplete, the prisoner may be convicted of a misdemeanor.

RAPE. This plant, which is of the cabbage tribe, is cultivated like cole, or colza, for the sake of its seeds, from which oil is extracted by grinding and pressure. It is also extensively cultivated in England for the succulent food which its thick and fleshy stem and leaves supply to sheep when other fodder is scarce.

The mode of cultivation of the colza and rape for seed is nearly the same. The colza takes a longer time to come to maturity, and produces more seed. The rape grows on less fertile soils, and may be sown in spring as well as in autumn. Both are hardy, and resist the winter's frost.

The colza (*Brassica oleracea*, or *campestris*) is a plant which grows with a strong branching stem, 3 or 4 feet high, and requires room to spread; and as cultivated in Belgium the plants are raised in a seed-bed, and transplanted when they have acquired a certain size. When rape (*Brassica napus*) is cultivated for the seed, it is treated in the same manner; one description will therefore serve for both.

The seed-bed, where the cultivation is on a small scale, is usually prepared by digging or trenching with the spade, in a good loamy soil, neither too sandy nor too wet. A large proportion of rotten dung is spread evenly over it, and dug in six inches deep, and the surface is raked fine. The seed is sown broad-cast or in drill; the latter is the best method: it is then slightly covered with the rake; and if the ground will allow of it, without risk of its being bound too hard in case of dry weather, it is well rolled or trod with the feet. The seed must not be sown too thick; and the plants, as soon as they have six leaves, must be thinned to a distance of four or five inches in the rows, which will make them stronger and better furnished with roots. One acre of seed-bed will furnish plants for ten acres or more. The seed is sown in July or August, that the plants may not run to seed the same year, which they are apt to do if sown early; and they are transplanted in September or October, on land which has already borne a profitable crop. As this crop is a substitute for a fallow on rich heavy land, too much pains cannot be taken to keep it free from weeds. Winter barley, and rye, which are reaped early in July, are very proper crops to be succeeded by rape or colza. The stubble should be ploughed two or three times, to pulverise and clean it. A good coat of rotten dung should be put on, and the land ploughed in ridges, as for turnips: the plants should be put in on the ridges ten inches apart. It requires great care in taking them up not to break the fibres of the roots: they should be raised with a fork, and placed gently, with the fine earth adhering to them, in flat baskets, and in a slanting position, so that the tops may be upwards. In planting, the holes should be made with a large thick dibble, that the plants may be introduced without doubling up the principal roots or breaking the fibres. The earth should be pressed to the root by a short dibble, inserted to the right or left of the hole made by the first dibble; or, which is better in stiff soils, a hole should be made with a narrow hoe of sufficient depth to allow the plant to be placed in it, and another hoe should follow to draw the earth to the plant. Thus two men with hoes, and one woman, will plant a row more rapidly than could be done any other way; the man who fills up the holes places his foot by the side of each plant as he goes on, to press the earth to the roots.

An expeditious mode of planting rape is used in Flanders. A spade ten inches wide is pushed vertically into the ground, and, by drawing the handle towards his body, the labourer makes a wedge-like opening; a woman inserts a plant in each side in this opening, and when the man removes the spade, the earth falls back against the plants. The woman puts her foot between the two plants, and they are then fixed in their places. In this operation the man moves backwards; and the woman, who puts in the plants, forward. Instead of the spade, an instrument is also used called a *plantoir*. It consists of two sharp-pointed stakes a foot or more apart, connected by a cross-handle at top, and a bar at about eight or ten inches from the points. The instrument is pressed into the ground by the handles, assisted by the foot placed on the lower bar, and makes two holes, a foot apart, into which the plants are placed, and earthed round as before. This is done when the land has not been laid up into high ridges.

When a large field is to be planted, a more expeditious mode is adopted; and this is the most usual practice in Holland and Germany. The land having been prepared, and the manure well incorporated, a deep furrow is drawn with the plough; women follow with baskets of plants, which they set, a foot apart, slanting against the furrow slice. When the plough returns, the earth is thrown against these plants; and a man or woman follows, who, with the foot, presses the earth down upon the roots. Sometimes plants are put into each furrow, which is then ten inches or more wide; but the best cultivators put them only in every alternate furrow. In this case also there are no ridges. The season of the year affords sufficient moisture in the north of Europe to ensure the growth of the plants; and if they have escaped the fly in the seed-bed, they are now tolerably safe. No further attention is requisite till spring. The weeds are then carefully extirpated by hand and hoe; and where the distance of the plants admits of it, the light plough stirs the ground between the rows, throwing the earth towards the stems, yet so as to leave each plant in a little basin to catch the water and conduct it to the roots. When the plants are invigorated with rich liquid manure, such as night soil mixed with water, or the drainings from dunghills, they become extremely luxuriant; and every trouble or expense bestowed upon them is amply repaid. The difference between a crop partially neglected and another carefully cultivated often exceeds fifty per cent.

There is not much difference between the value of colza and rape-seed (called *navette* in French); but the latter produces less. When the rape is transplanted before winter, it is much more productive than when sown in spring. In the latter case it produces seed the same year. It is sown in drills, and thinned out by the hoe, and in favourable seasons a tolerable crop is obtained. It is generally sown on land which could not be brought into a proper tilth after harvest, and which would require the frost of winter to mellow it.

Great crops of cole-seed and rape have been produced in the fens of Lincolnshire and the alluvial soils in Essex, by merely paring and burning the surface and ploughing in the ashes; and these crops, alternating with oats, have in many instances so exhausted the soil as to cause a great prejudice against them in the minds of the landlords. Many leases have a clause prohibiting their cultivation, except to be eaten green by sheep. The principal cause, however, of the diminution of this crop in England is the inferior price obtained for the seed when compared with wheat, which can be raised on the same land, and is a more certain crop.

The rape and colza ripen their seed very unequally. The lower pods are ready to burst before those at top are full. If the season is wet at harvest, much of the seed is lost; and, without great attention, some loss is sustained in the most favourable seasons. It should be cut when the dew is on it, and moved as little as possible. If the weather permits, it is threshed out on a cloth in the field, and as many threshers are employed as can be conveniently collected, that no time may be lost, when the weather is fair. The seed is spread out on the floor of a granary that it may not heat, and is turned over frequently. It is then sold to the crushers, who express the oil. The pods and small branches broken off in threshing are much relished by cattle. This crop returns little to the land, and is of itself very exhausting. Not so, however, is the rape, when sown as food for sheep. It is, on the contrary, a valuable substitute for turnips, upon land which is too wet and heavy for this root. The *Brassica oleracea* is more succulent than the *Brassica napus*. Its stem is not so hard, and the soft pith which it contains is much relished by every kind of live-stock. To have it in perfection, the land should be prepared and manured as for turnips. The rape should be sown in drills ten inches apart, in June, July, or August. It will be fit for consumption before winter, during winter, or after winter, according to the period of its seedtime. In the last case, in the end of March and beginning of April it will be a great help to the ewes and lambs. It will produce excellent food till it begins to be in flower, when it should immediately be ploughed up. The ground will be found greatly recruited by this crop, which has taken nothing from it and has added much by the dung and urine of the sheep. Whatever be the succeeding crop, it cannot fail to be productive; and if the land is not clean, the farmer must not have neglected the double opportunity of destroying weeds in the preceding summer and in the early part of spring. If the rape is fed off in time, it may be succeeded by barley or oats with clover or grass seeds, or potatoes, if the soil is not too wet. Thus, no crop will be lost, and the rape will have been a clear addition to the produce of the land. Any crop which is taken off the land in a green state, especially if it be fed off with sheep, may be repeated, without risk of failure, provided the land be properly tilled; but where cole or rape have produced seed, they cannot be profitably sown in less than five or six years after on the same land.

When the oil has been pressed out from the seed, the residue (which contains a portion of starch and mucilage not changed into oil) and the husk of the seed form a hard cake known by the name of rape-cake. This has been long used on the Continent, and has lately in this country been used, to feed cows and pigs with, as we use the linseed-cakes: but it is also much used as a rich manure, and for this purpose it is imported in large quantities. When rape-cake is ground to a powder and drilled with the seed on poor light lands, it supplies nourishment to the young plants, and greatly accelerates their growth; but if it be added in a large proportion in immediate contact with the seed, on heavy impervious soils, it often undergoes the putrid fermentation, which it communicates to the seed sown, and, instead of nourishing, destroys it. In this case it is useful to mix it with some dry porous earth or with ashes, which will prevent the too rapid decomposition. Dissolved in water and mixed with urine, it forms one of the most efficacious of artificial liquid manures. Hence it is probable that the most advantageous mode of using it on the land, after it has been dissolved in the urine-tank, is to apply it by means of a water-cart to the rows where the seed has been already drilled, or some time before it is put in. Where flax is to be sown, this mixture applied a few days before the seed is sown, so as to allow it to sink into the soil, is considered in Flanders as next in value to the emptyings of privies, which with them hold the first rank, for producing fine crops of flax. When a crop appears sickly, and not growing as it should do, owing to poverty in the soil, a top-dressing of rape-cake dissolved in water, if no urine is at hand, will in general excite the powers of vegetation; and it is highly probable that it may greatly assist the effects of saltpetre or of nitrate of soda, where these salts are applied. The cultivation of rape or cole for spring food cannot be too strongly recommended to the farmers of heavy clay soils.

RAPE-SEED. The *Brassica napus*, the plant which produces the rape-seed, and which is of the cabbage tribe, is cultivated like Cole, or Colza (*Brassica napus sativa*), for the sake of its seeds, from which oil is extracted by grinding and pressure. It is also extensively cultivated in England for the succulent food which its thick and fleshy stem and leaves supply to sheep when other fodder is scarce. The mode of cultivation of the colza and rape for seed is nearly the same. The colza takes a longer time to come to maturity, and produces more seed. The rape grows on less fertile soils, and may be sown in spring as well as in autumn. Both are hardy, and resist the winter's frost.

The rape seed imported in the years 1857-8-9 averaged 283,000 qrs. per annum: it is admitted free of duty.

RAREFACTION is an augmentation of the intervals between the particles of aeriform fluids, so that the same number of particles are made to occupy a volume greater than that under which they were previously contained. The term is used in opposition to *condensation*, and in the same sense as *dilatation*, which last is applied both to fluids and solids. Rarefaction or dilatation is caused by a repulsive power existing either in the particles of bodies or in those of the caloric between them, by which power the particles are made to recede from one another when not prevented by some external resistance. [ATTRACTION.]

The experiments of Lavoisier and Laplace have shown that, between the temperatures of freezing and of boiling water, the dilatations of all metals and of the fluids called non-elastic are constantly proportional to the increments of temperature; but beyond the temperature of boiling water the experiments of Dulong and Petit indicate that the dilatations increase in a higher ratio. A remarkable circumstance is observed in the state of water when near congelation. On being cooled to a temperature of about 38°·8 of Fahr., its volume remains stationary through a small range, and in this state water seems to have attained its *maximum of density*; for, on continuing the cooling process, the water begins to expand, and it continues to do so until it is converted into ice. In fact, just before water freezes it occupies a space as great as it did at 48°. If water at 39°·2 be taken as 1, at 32° its density = 0·99988.

From the experiments of M. Gay-Lussac and Dr. Dalton it has been ascertained that, under equal external pressures, the rarefactions of all dry gases and of the aeriform substances produced by the evaporation of liquids are equal at equal temperatures, between the points of freezing and boiling water, and that they vary in volume proportionally to the increments of heat expressed by the expansions of mercury in the thermometer. [AIR; HEAT; GAS; PNEUMATICS.]

The density or closeness of the aerial particles in any given portion of the atmosphere depends on the pressure or weight of the column of air above the given point; and by the law of Boyle or Mariotte, whatever be the temperature, provided it be constant, the density is proportional to the pressure; or, conversely, the rarefaction is inversely proportional to the pressure. It has been proved [PNEUMATICS] that the densities of the strata of air decrease upwards in a geometrical progression when the altitudes of the strata increase by equal increments; and this is equivalent to saying that the rarefactions of the air at such altitudes increase in a geometrical progression. Now if A be any point on the surface of the earth, and C any point above it, the formula AC (in fathoms) $= 10670 \times \log. \dfrac{\textit{density at } A}{\textit{density at } C}$ [PNEUMATICS], will afford the means of computing the rarefaction of the air at any point C, when its height above A is given. But if the density at A be considered as unity (the temperature being = 55°) the equation may be transformed into

$$\frac{AC}{10670}\left(=\log.\ \frac{1}{\textit{density at } C}\right)=\log.\ \textit{rarefaction at } C,$$

in which, substituting for A C any given value in fathoms, the rarefaction may be found. For example, let A C = 3212 fathoms (3·65 miles); then the second member of the equation will become ·30103 (= log. 2), which shows that at the height of about 3⅔ miles the rarefaction of the atmosphere is twice as great as at the surface of the earth; and by forming the progression of heights—

0 , 3·65 , 7·3 , 14·6, &c. in miles,

we have for the corresponding rarefactions—

1 , 2 , 4 , 8, &c.

For the rarefaction of the air in an air-pump, after any number of strokes of the piston, see AIR-PUMP.

The limits to which rarefaction may be carried are unknown, but the experiments of Mr. Boyle and others have proved that, by simply removing the external pressure, air may be so rarified that a given volume of the same density as at the surface of the earth will occupy a volume more than 13,000 times as great. It has been however discovered that at very high degrees of rarefaction the elasticity of the air decreases in a higher ratio than the density; and this may serve to prove that rarefaction cannot take place to an infinite extent. [ATMOSPHERE.]

RASP. [FILE MANUFACTURE.]

RASPBERRY. The species from which the cultivated varieties of this fruit have been derived is the *Rubus Idæus*, a native of Britain and also of various other parts of Europe. The wide dispersion of the species is easily accounted for from the fact of its seeds resisting the powers of digestion in an eminent degree.

For a selection, the following varieties may be enumerated:—Red Antwerp, Yellow Antwerp, Barnet, Double Bearing, and Wilmot's early Red.

The best soil for raspberries is a light rich loam. They will thrive well in sandy peat, provided it is not too dry. In all cases the ground for a plantation should be well trenched and manured previous to planting. The plants from suckers, of which there are generally abundance, should be planted in rows five or six feet apart, and four feet from plant to plant in the row. When planted they should be cut to within six inches of the ground; for although this is not absolutely essential, yet by so doing the shoots for the following season are greatly strengthened.

Pruning should be performed in autumn. It consists in first clearing off all dead portions, and retaining only from four to six of the strongest summer shoots of each plant, which should be shortened according to their strength, generally at a bend, which indicates where the shoot becomes weak, near the extremity. In the following summer the shoots just mentioned bear the fruit, whilst others spring up at their base for a succession; and in all cases succession shoots should be disposed so as neither to crowd the fruiting portion nor each other. Stakes should be driven for the support of the plants, to which they should be loosely bound.

The ground of a raspberry plantation should be kept loose and supplied with well-rotted manure, but in so doing a fork should be used in preference to a spade, in order to preserve the roots as much as possible, and the roots should not be at all disturbed after active vegetation takes place in spring. Notwithstanding the best management in these respects, it becomes adviseable to make a new plantation in fresh soil after four or five years; for the roots diffuse themselves so thoroughly in every portion of the soil near the stools, that it soon becomes exhausted.

The fruit of the raspberry is extensively used in a variety of ways, both by the cook and the confectioner, and also in the preparation of cordial spirituous liquors.

RATAFIA is a liqueur prepared by flavouring sweetened spirit with various kinds of fruit. There are many varieties, generally named after the fruit which is employed: *Ratafia de Cassis* has cherries; *Ratafia de Curaçoa* has the peels of Portugal oranges; *Ratafia d' Angelique* has Angelica seeds; *Ratafia d'Anis* has aniseed; and so on. There are ratafias not only of fruits but of seeds, berries, flowers, balsams, and other vegetable products. There are ratafias, for instance, of cherries, quinces, raspberry, juniper, walnuts, peach and apricot kernels, coffee, cocoa, clovepinks, Seville orange peel, orange flowers, violets, Tolu balsam, &c. All these ratafias have spice and sugar added to them. The French liqueurists are skilled in this as in most other branches of delicate distillation and making of essences. Many English processes of this kind come under the name of *rectifying*, as described under DISTILLERY.

RATE, an assessment levied upon property. Rates are of various kinds, and are denominated with reference to the objects to which they are applied.

Church-rates are payable by the parishioners and occupiers of the land within a parish, for the purpose of repairing, maintaining, and restoring the body of the church and the belfry, the churchyard fence, the bells, seats, and ornaments, and of defraying the expenses attending the service of the church. The duty of repairing and rebuilding the chancel devolves on the rector, or vicar, or both together, in proportion to their benefice, where there are both in the same church. But by custom the parishioners may be liable to repair the chancel; and in London there is a general custom to that effect. Church-rate exists in England by virtue of the common law; nothing is known as to its commencement or introduction.

In the early church there appears to have been a division of the tithes—either tripartite, one portion to the clergy, one to repairs of the church, and one to the poor; or quadripartite, one to the bishop, the other three to the clergy, the church, and the poor. At that time the bishop resided at the cathedral church, together with his clergy, and on him devolved the duty of repairing the church, caring for the poor, and supplying ecclesiastical ministry. It was then the duty of every Christian man to pay to the bishop not only the decimæ, or tithes, but also the ecclesiæ census, church-scot, and the nummus eleemosynarius (alms money). The object to which church-scot was devoted is not known; but church-rates, or something equivalent, certainly appear to have been in existence as a payment by the laity, independent of tithes, in the time of Canute, whose 63rd law, "de fano reficiendo," states that all persons ought of right to contribute to the repair of churches.

Church-rates are imposed by the parishioners themselves at a meeting summoned by the churchwardens for that purpose, and a mandamus is grantable to compel such meeting to be held. If the parish fail to meet, the churchwardens may impose a rate, but if the meeting should assemble, it rests with the parishioners themselves to determine the amount of the rate; and they have authority to negative the imposition of a rate altogether; the only mode of compelling them to impose a rate being by ecclesiastical censures and laying the parish under interdict. The existing poor-rate of the parish is generally taken as the criterion for the imposition of the church-rate. All property in the parish is liable except the glebe-land of that parish and the possessions of the crown. The ecclesiastical courts have the exclusive authority of deciding on the validity of a rate, and the liability of a party to pay it; but a rate-payer cannot by an original proceeding in those courts raise objections to a rate for the purpose of quashing it altogether. If he wishes to dispute it, he ought to attend at the vestry, and there state his objections; if they are not removed, he may enter a caveat against the confirmation of the rate, or refuse to pay his assessment. In the latter case, if proceeded against in the ecclesiastical court, he may in his defence show either that the rate is generally invalid, or that he is unfairly assessed. The consequence of entering a caveat is an appeal to the ecclesiastical judge, who will see that right is done. Previously to 53 Geo. III., c. 127, the only mode of recovering church-rates from parties refusing to pay was by suit in the ecclesiastical court for subtraction of rate. By that statute, where the sum to be recovered is under 10*l.*, and there is no question as to the validity of the rate, or the liability of the party assessed, any justice of the county where the church is situated may, on complaint of the churchwarden, inquire into the merits of the case, and order the payment. Against his decision there is an appeal to the quarter-sessions. As to other rates, see SEWERS; SHIRE; WAY.

(Lyndwood; John de Athon: Selden's *History of Tithes;* Gibson's *Codex;* Burn's *Ecclesiastical Law;* Rogers's *Ecclesiastical Law*, 1840.)

RATIO. One of the most frequent mathematical terms has no other name in our language than a Latin word which is but a bad translation from the Greek of Euclid. The older English writers introduced the word *reason*, as a translation of ratio, which completed the confusion; for it is easier to attach any meaning we please to a word in a dead language than to the literal translation of it in our own.

The word ratio is the translation of *λόγος*, as used in the third definition of the fifth book of Euclid, which is *Λόγος ἐστὶ δύο μεγεθῶν ὁμογενῶν ἡ κατὰ πηλικότητα πρὸς ἄλληλα ποιὰ σχέσις.* This has been translated by English writers, "Ratio is a mutual habitude of two magnitudes of the same kind with respect to quantity." By Gregory, in his translation which accompanies the Greek, "Ratio est duarum magnitudinum ejusdem generis secundum *quantuplicitatem* mutua quædam habitudo."

The common translation is unmeaning; and it will be worth while to offer some remarks on the probable meaning of Euclid. In the first place, let it be observed that he never attempts this vague sort of definition except when, dealing with a well-known term of common life, he wishes to bring it into geometry with something like an expressed meaning, which may aid the conception of the thing, even though it does not furnish a perfect criterion. Thus, when in speaking of a straight line, he says that it is the line which lies evenly (*ἐξίσου κεῖται*) between its extreme points, he merely calls the reader's attention to the well known term *εὐθεῖα γραμμή*, tries how far he can present the conception which accompanies it in other words, and trusts for the correct use of the term to the axioms which the universal conception of a straight line makes self-evident. Let us suppose him doing the same thing here, and we shall find that the definition before us, considered with reference to the place it is in, and the subsequent purpose which it serves, is as clear as the translation of it is confused.

The term *λόγος* contains (*λεγ, λογ*), a root the original meaning of which seems to have contained the idea of collection or bringing together. It is certain however that the secondary sense which it obtained in common usage was that of speaking; so that the first sense in which *λόγος* appears in writings is that of speech. Subsequently, speech being the distinctive character of reasoning beings, and their mode of communication, the word was applied to every sort of communication, not only with reference to the mode of communication, but also to its subject; thus explanation, defence, apology, teaching, assignment of cause or reason, &c., are among the recognised uses of the word. The Latin translators have taken the geometrical word as being properly translated by *ratio*, a word which may very well signify the technical meaning of *λόγος*, but has no reference to its primary meaning. For ratio, in its primitive sense, means rather computation or reckoning than reason.

But what has speech to do with the sense of ratio in geometry? Robert Recorde answers this question [NUMERATION], when he reduces his pupil to silence by forbidding him the use of number, and asking him questions. Numbers are but certain ratios, and ratio is a generalised idea of number. Our gift of speech with reference to magnitudes would be altogether annihilated if we did not consider a certain habitude or mode of existence which they have, or more correctly a certain conception of our own, which always accompanies the presence of two magnitudes, and prompts us to inquire how many times one is contained in the other. A foot being known, speech can carry a correct knowledge of other lengths all over the world; but let it be attempted to describe a foot in words without reference *κατὰ πηλικότητα* to some other magnitude, and all the powers of language utterly fail. We conceive then that in this definition Euclid simply conveys the fact that the mode of expressing quantity in terms of quantity, is entirely based upon the notion of *quantuplicity*, or that relation of which we take cognizance when we find how many times one is contained in the other.

The word *πηλικότης* has been translated "quantity," by many editors, which makes nonsense of the whole; for magnitude has hardly a different meaning from quantity, and a relation of magnitudes with respect to quantity may give clear ideas to those who want a word to convey a notion of architecture with respect to building, or of battles with respect to fighting; and to no others. Wallis, we believe, restored the true meaning of the word, and was followed by Gregory, as seen above: and Euclid himself, or some very old commentator, in another place, shows in what sense he used it. In the fifth definition of the sixth book (omitted by many editors), he says that a ratio is compounded of two other ratios when the *πηλικότητες* of the latter *multiplied* (*πολλαπλασιασθεῖσαι*) together, make the former. Now, this would be unmeaning if the Greek word meant simply quantities, unless they were quantities represented by numbers (though Gregory has here forgotten his own previous correction, and writes quantitas instead of quantuplicitas). The lexicographers generally give "quantitas;" but they are not adepts in the mathematical use of terms implying relations of magnitude.

The first and rough notion of ratio being thus given, we may find a synonyme for the word in the more intelligible term *relative magnitude*. Six feet, though greater than three feet, is, relatively to four feet, a less magnitude than three feet is, relatively to one foot: the number of times which six feet contains four feet is less than the number of times which three feet contains one foot. The relative magnitude of six to four is less than the relative magnitude of three to one; or the ratio of six to four is less than the ratio of three to one.

Given two magnitudes, how are we to find the means of expressing the first in terms of the second? Euclid answers this question, when it can be answered, in the tenth book, by giving the rule for finding the greatest common measure of two magnitudes, in which he employs a process exactly the same as that of the arithmetical rule in common use. Of two magnitudes which are multiples of the same third magnitude, each is a definite arithmetical fraction of the other.

But it may happen that the magnitudes have no common measure [INCOMMENSURABLE], in which case the means of expression would fail. We can describe the diagonal of a square as a part of a certain figure, and the description is perfect; but if we attempted a description *secundum quantuplicitatem*, we should never succeed; for no possible line exists of which it can be said that the diagonal of a square and its side both contain that line exactly. Such quantities are called by Euclid *ἄλογα*, irrational, or having no ratio; and in the primitive meaning of the term this is correct, for there is no quantuplicitative mode of expressing one by the other. But the term ratio, both in Euclid and all other writers, immediately acquires another sense; and it is this new sense in which we proceed to speak of ratio. Since the relative magnitude of two quantities is always shown by the quantuplicitative mode of expression, when that is possible, and since proportional quantities (pairs which have the same relative magnitude) are pairs which have the same mode (if possible) of expression by means of each other; in all such cases sameness of relative magnitude leads to sameness of mode of expression; or proportion is sameness of ratios (in the primitive sense). But sameness of relative magnitude may exist where quantuplicitative expression is impossible; thus the diagonal of a larger square is the same compared with its side as the diagonal of a smaller square compared with *its* side. It is an easy transition to speak of sameness of ratio even in this case; that is, to use the term ratio in the sense of relative magnitude, that word having originally only a reference to the mode of expressing relative magnitude, in cases which allow of a particular mode of expression. The word irrational does not make any corresponding change, but continues to have its primitive meaning, namely, incapable of quantuplicitative expression. And it is worth noting that this of itself shows that the original meaning of *λόγος* referred to expression, not to the thing expressed; for *ἄλογα* (not having a ratio) would have been absurd as applied to incommensurable quantities, if the primitive mathematical meaning of the first word had coincided with its modern one.

The idea of relative magnitude is one which strikes us in all cases in which we compare the parts of an original with the corresponding parts of any model or imitation. It does not closely connect itself with any mode of expression or measurement: if a part of the model were only in a slight degree too large or too small, the detection of the error might require a formal measurement, but anything which is very much out would be rejected by one glance of the eye. Let us suppose now that the formal measurement is attempted. The first and simplest notions of relative magnitude are gained from repetition; and the ideas of two, three, four, &c., originally used in their simple cumulative sense, soon become the representatives of those simple relative magnitudes which are suggested by pairs in which one is quantuple of the other. The next step is to those magnitudes in which neither is quantuple of the other, but both are quantuple of a third: from which we learn how, admitting aliquot parts, to extend the mode of expression. Thus, of the magnitudes 10 R and 7 R, we see that every relation of quantuplicity can be derived from the simple numbers 10 and 7: the first number is $1\frac{3}{7}$ of the second, a mode of expression which equally applies to the magnitudes 10 R and 7 R.

Let D and S be two incommensurable magnitudes: how are we to describe their relative magnitudes? That they have a definite relation is certain; suppose, for precision, that S is the side of a square, and D its diagonal; any alteration of D, or any error in D, S being given, would make the figure cease to be a square. There are many mathematical notions in which accuracy is not attainable in finite terms, but is the limit towards which we approach when number or magnitude, as the case may be, is increased or diminished without limit. In the present case the expression of ratio or relative magnitude, which is not accurately attainable by one or more relations, can be continually amended by adding one or more relations, until the inaccuracy of the mode of expression is rendered as small as we please; in such a case, accuracy must be imagined to reside in the supposition of an infinite number of given, or at least of attainable, relations.

To explain our meaning, suppose that the person whom we address is altogether ignorant of the relative magnitude of the diagonal D and the side S. He asks for a relation, and knowing the mode of dealing with the ratios of commensurables, naturally desires to know how many diagonals make an exact number of sides. If we could answer this question, if for instance we could say that 100 diagonals make 142 sides exactly, the question would be settled: for an arithmetical rule would always deduce the diagonal when the side is given. But we are obliged to reply, that no number of diagonals whatsoever will make an exact number of sides. He then asks how he is to form a perfect conception of the diagonal; we answer by placing two equal sides at right angles to one another, and joining the extremities. This, he replies, and properly, is not a mode of finding the relative magnitude, which is something connected with magnitudes only, and that the permission given by Euclid to join two given or determined points is not any real determination of the included length. We then tell him that it is at his pleasure to name a fraction of the side, and we can express the diagonal with an error not so great as that fraction; he names, say one-millionth of the side, and we give him the promised information in telling him that 1,000,000 of diagonals exceed 1,414,213 sides, but fall short of 1,414,214 sides. The consequence is, that the diagonal lies between 1·414213 and 1·414214 of the side: these differ from one another by one-millionth of the side, and the error of the diagonal is of course less. If he should ask how he is to carry this process yet further for himself, we give him the arithmetical symbol $\sqrt{2}$, and instruct him how to perform the arithmetical operation of approximating to its value. In this we show him how to find between what number of sides any number of diagonals lies; and in so doing we give the ratio of the diagonal to the side, so far as the nature of the case will admit of its expression.

The relative magnitude, then, of two magnitudes is given, when the place of any multiple whatsoever of the one among the multiples of the other can be found from the data. For example, we carry on the *multiple scale* of the side and diagonal of a square, in the power of extending which *ad infinitum* lies that of expressing the ratio, so far as expression is possible, and of absolutely comparing the ratio with others, in as accurate a manner as if expression had been perfect.

> S, D, 2S, 2D, 3S, 4S, 3D, 5S, 4D, 6S, 7S, 5D, 8S, 6D, 9S, 7D, 10S, 11S, 8D, 12S, 9D, 13S, 14S, 10D, 15S, 11D, 16S, 12D, 17S, 18S, 13D, 19S, 14D, 20S, 21S, 15D, &c.

In this table we see, for instance, that 10 diagonals are more than 14 and less than 15 sides, and so on. The only doubt that can possibly remain may be thus expressed:—Is the preceding scale a property of the diagonal and of nothing else? May there not be a length so near to the diagonal that its multiples shall never fall out of the same intervals as those of the diagonal? Let K be a given quantity, no matter how small; we say that it is impossible that all the multiples of D + K can lie in the same places among the multiples of S as the multiples of D. Take *m* times both; then *m* (D + K) and *m*D differ by *m*K. Now however small K may be, it is possible to take *m* so great that *m*K shall exceed S, or any multiple of S previously named: whence the thing asserted is evident. The definition of the ratio of S to D lies, then, in this scale; or rather, whatever the definition may be, the mode of finding all relations between S and D lies in the formation of this scale so far as may be necessary for the purpose in hand. The definition of proportion is then contained in sameness of multiple scales; that is, D is to S as A to B, when any multiple whatever of D is contained between the same two multiples of S, that the same multiple of A is contained between those of B. We here come to the subject of PROPORTION, which the reader should now consult as a continuation of the present one.

It is well known that the word λόγος came to mean *fraction*, the expression of commensurable ratio. Fractional arithmetic was called *logistic* arithmetic even down to the 17th century. It is not so well known that this use of the word is as old as the time of Euclid. Aristotle gives, as his instances of discontinuous quantity, *ἀριθμός καὶ λόγος*, number and fraction. The logicians have always taken this to mean number *and speech*, some transcriber having interpolated a subsequent passage to this effect in the text of Aristotle. Plato tells us that the Egyptian Theuth invented *ἀριθμόν τε καὶ λογισμός*, meaning, no doubt, integer and fractional reckoning. The idea implied in composition of ratio is very imperfectly treated in Euclid: and yet upon the correct understanding of it depends whether the boasted victory over the difficulties of incommensurables which the fifth book gives is real or imaginary.

In every matter connected with elementary geometry, confusion may and often does arise from mixing together criticisms of two different kinds; on Euclid as a writer, and on the subject as a matter of thought. To avoid such confusion in reference to composition of ratio, we shall begin with the consideration of what we find in Euclid,—not in Simson's Euclid, nor Playfair's Euclid—but in Euclid of Alexandria.

There is nothing on ratio compounded (*συγκειμένος*) of ratios in the fifth book; the word translated composition (*σύνθεσις*) refers to such a process as the formation of the ratio of A + B to B from that of A to B. But the definitions of duplicate, triplicate, &c. ratio, are laid down; which, as we shall see, are particular cases of compound ratio. These definitions are as follows:—if A, B, C, D, &c., be in continued proportion, so that as A to B, so B to C, C to D, and so on, then the ratio of A to C is called the duplicate ratio of that of A to B, the ratio of A to D is called the triplicate ratio of A to B, and so on.

In one proposition, and in one only, is the phrase composition of ratios used: in the 23rd of the sixth book, where it is said "Equiangular parallelograms have to one another the *ratio compounded of the sides.*" There is no definition (at least, it is now so supposed; here however we must refer to our next paragraph) given of the words in italics, and on looking into the demonstration of the proposition, we find we must assume, as a matter of phraseology merely, that of any three quantities of the same kind, K, L, M, we are to say the ratio of K to M is compounded of the ratios of K to L and of L to M. And further that if A be to B as K to L, and V to W as L to M, then the ratio K to M is said to be the ratio compounded of the ratios of A to B and of V to W. If there be anything more than mere phraseology in this, it must be because Euclid makes a tacit reference to some arithmetical system current in his time.

It is true that there is found in a great preponderance of manuscripts (in all, we believe) a definition of compound ratio. It is among the definitions of the sixth book, and literally translated* is as follows:—"A ratio is said to be compounded of ratios, when the *πηλικότητες* of the ratios multiplied together make a certain [ratio]." On the word left untranslated (which, we believe, must be translated by *quantuplicities*), we refer to what precedes and to what follows. This definition is admitted into the editions of Basel and Oxford, and into Briggs's edition of the six books. Peyrard has omitted it in the Paris edition, because, in his celebrated Vatican manuscript, it is not in the text, but has been added at the side. The Berlin editor admits it in parentheses as a disputable passage. Set a scholar to make the text of Euclid from the ordinary mode of weighing the evidence of manuscripts, and there is no doubt this definition must appear as a part of the elements. Set a geometrical reasoner to settle the question by the internal evidence of the passage and its keeping with the rest of the book, and there is as little doubt that it would be rejected. The meaning of the passage is, apparently, that if two ratios be expressed numerically, as those of 7 to 4 and 6 to 11, the ratio compounded of those ratios is to be the ratio of 7 × 6 to 4 × 11; or possibly, that, expressing the above ratios as those of $\frac{7}{4}$ to 1, and $\frac{6}{11}$ to 1, the compounded ratio is that of $\frac{7}{4} \times \frac{6}{11}$ to 1.

In the early translations from the Arabic, the definition is omitted, and reference is made, in demonstrating vi. 23, to a note inserted among the definitions of the fifth book, which is very insufficient. But the phrase there is that the ratio of *f* to *h* is *produced* from those of *f* to *g* and *g* to *h*: and to the definitions of the seventh book several are added, one of which is, that in a series of numbers the ratio of the first to the last is produced from the successive ratios of each to the one following.

In many manuscripts there is a scholium preceding the sixth book, which August, the Berlin editor, though not admitting it into Euclid, thinks must be of high antiquity; in which we fully agree with him. It is to be found in the Basel edition, and in the notes to the Berlin. This scholium, while it gives confirmation to the preceding view (which hardly wants it), takes the same side on the meaning of the word *πηλικότης* as we have done. And we find that Wallis was the person who suggested to Gregory *quantuplicitas* instead of *quantitas* as the translation. See his discussion of this point at length in his English Algebra (1684), ch. 19 and 20; revised in his Latin Algebra (Works, vol. ii. ch. 19, 20), and again at p. 665 of the same volume, where there is a defence of this definition against Henry Savile, who (Prælect. in Eucl.) had considered it as a great defect. To the text of Euclid we have only further to say that this consent of Savile, Wallis, and Gregory, as to the genuineness of the definition in question, is of great weight. But with regard to the matter of the definition we agree entirely with Savile. The word *πηλικότης* needs definition quite as much as the phrase *composition of ratios* itself. This definition, it will be observed, either restricts the composition to ratios which are of commensurable magnitudes, or implies and assumes the multiplication of two interminable decimal fractions. An old scholiast on

---

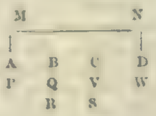
* *Λόγος ἐκ λόγων συγκεῖσθαι λέγεται ὅταν αἱ τῶν λόγων πηλικότητες ἐπ' ἑαυτὰς πολλαπλασιασθεῖσαι ποιῶσί τινα.* The Scholium presently cited gives it with *λόγον* for *τινα* in one place, and *πηλικότητα λόγου* in another.

Euclid (cited from Dasypodius by Meibomius and Wallis) is of opinion that πηλικότης is used rather than the more natural word ποσότης, precisely that it may be understood in a wider sense, so as to include fractional and incommensurable ratios. That is, as Wallis expresses it, *how-much-fold* is used instead of *how-many-fold*, that *much* may suggest the idea of a part of a time (commensurable or not) where *many* would only suggest that of an integer. We cannot much admire this refinement; nor does it give any help: for the introduction of the idea of *incommensurability* numerically expressed, so as to be fit for arithmetical multiplication, would vitiate, or at least would transmute, Euclid's whole system of proportion.

But the oldest testimony, both to the existence of the definition, and the meaning of the disputed word, is Eutocius, in his commentary on book ii. prop. 5 (of Torelli, 4 of preceding editors). He here cites, expressly from the elements, the definition as given; and adds, as the explanation of πηλικότης, that it is the number which, by multiplication, turns the consequent into the antecedent. This number, he says, gives name to the ratio, and he cites Nicomachus and Heron as understanding it in the same way. But, he goes on to say, the word is more properly taken when this number is an integer.

Leaving now out of view what Euclid really did write, we shall proceed to consider the subject of composition of ratios, so as to supply what, on any supposition, must be acknowledged to be wanted in the elements. The notion of a ratio is easily and almost necessarily connected with the idea of alteration *in that ratio*. We cannot express a ratio without two magnitudes, the first of which, altered in the ratio given, becomes the second. If we want to alter in the ratio of P to Q, this is easily done when the quantity to be altered is P; for then the process is only writing Q instead of P. But if the quantity be A, then B must be found, so that A and B shall have the same ratio as P and Q.

If it be a numerical ratio which we consider, say that of 3 to 5, alteration of any number in that ratio implies that we change all its *threes* into *fives*, and any remaining fraction of three into the same fraction of five. Alteration of any magnitude, say a length, in that ratio implies that, choosing any length as a measure, we alter every three such lengths which the given magnitude contains into five, and every fraction of three into the same fraction of five. This amounts to changing the number or magnitude into five-thirds of what it was; and generally, alteration in the ratio of a to b (numbers) is nothing but multiplication by $\frac{b}{a}$



Take a magnitude A, alter it in the ratio of P to Q: say that it then becomes B; that is, A is to B as P to Q. Take the magnitude we left off with, B, alter it in the ratio of R to S, making it C. Take C, alter it in the ratio of V to W, making it D. Then at three processes, by three successive alterations dictated by given ratios, we have changed A into D, or have altered A in the ratio of A to D. Say that the ratio of A to D is more simply expressed by that of M to N. Then, if we begin with A, and alter it at once in the ratio of M to N, we change it into D, producing the same effect as if we had successively altered in the ratios of P to Q, R to S, and V to W. Hence the ratio of M to N is properly said to be compounded of the ratios of P to Q, R to S, and V to W,: it dictates the alteration which will produce at once the effect of the three alterations prescribed by the three other ratios. In like manner, we say as to *addition*, that 10 is compounded of 6 and 4; for addition of 10 is equivalent to the addition of 6 and of 4. In multiplication we say that 24 is compounded of 6 and 4. And generally, the compound should be defined as that which produces the united effect of all the components, when both components and compound are used in the same way. Euclid, vi. 23, is now more than a mere addition, to the phraseology of geometry. The parallelograms A B C D and E F G H [the reader may draw the figure for himself] being mutually equiangular, it tells us that if we take any magnitude and alter it in the ratio of A C to E G, and then alter the result in the ratio of A B to E F, the change thus made at two steps might be made in one by altering the original magnitude in the ratio of the area A B C D to the area E F G H.

This process applies equally to commensurable and incommensurable ratios; but in the former case of course the arithmetical substitute for composition of ratios is easy. We want to compound the ratios of m to n and of a to b, all four being integer numbers: it being known that every commensurable ratio is expressible by the ratio of two integer numbers. Take any magnitude P, and alter it in the ratio of m to n: it becomes n-$m$ths of P. Alter this in the ratio of a to b: we have then b-$a$ths of n-$m$ths of P, or bn-amths of P, which would also be obtained by altering P in the ratio of $a \times m$ to $b \times n$. Hence composition of numerical ratios is performed by multiplication of the antecedents for an antecedent and of the consequents for a consequent. The process then is merely equivalent to that of the multiplication of fractions. If $\frac{n}{m}$ and $\frac{b}{a}$ were called the quantuplicities (πηλικότητες) of the ratios, then the quantuplicity of the compound ratio is the product of the quantuplicities of the components, as in the definition (be it Euclid's or no) which is found in the manuscripts of the elements.

Duplicate ratio (διπλασίων λόγος) has been defined by Euclid in the manner hereinbefore given. But it is in fact the ratio arising from the composition of two equal ratios. Suppose we want to compound the ratio of P to Q with the ratio of P to Q. Take a magnitude to begin with, which may as well be P itself: alter it in the ratio of P to Q; it then becomes Q. Alter Q into R in the ratio of P to Q; that is, let R be a third proportional to P and Q. Then P is changed into R at these two steps, each involving an alteration in the ratio of P to Q: hence Euclid's duplicate ratio is the ratio compounded of two equal ratios; and, similarly, triplicate ratio (τριπλασίων) is that compounded of three equal ratios, and so on.

The subduplicate, subtriplicate, sesquiplicate, &c. ratios, which later geometers used, completed that language of multiplication and division applied to operations of powers and roots which finally suggested the idea of logarithms. [See also Addition of Ratios.]

The propositions requisite for the establishment of the direct use of compound ratio are contained in the fifth book. But in the inverse use there is a manifest hiatus in the converse part of vi. 22. It is supplied by a lemma added at the end of the proposition; which is found in almost all the manuscripts (even in the Vatican manuscript, and Peyrard admits it accordingly). This is a pretty sure sign that Euclid did not give the lemma; for he never refers to anything which is to come after what he has in hand. Robert Simson omits this lemma, and so leaves the proposition undemonstrated. What is wanted is the following:—It is impossible that the same ratio should have two sub-duplicate ratios, or should be the duplicate ratio of two different ratios; or, if A be to B in the duplicate ratio of A to X, and also in the duplicate ratio of A to Y, then X and Y must be equal. If possible, let them be unequal; say that X is the greater:

A X B
A Y B

Then because X is greater than Y, the ratio of A to X is less than that of A to Y. But the ratio of A to X is that of X to B; and the ratio of A to Y is that of Y to B; therefore the ratio of X to B is less than that of Y to B. Therefore X is less than Y; but it is also greater, which is absurd. Consequently X and Y cannot be unequal, &c. By a continuation of this process it may easily be established that a given ratio can only be the triplicate of one ratio, only the quadruplicate of one, and so on.

It is unnecessary to say anything on the *decomposition* of ratios. Clear as it becomes in arithmetic, after a while, that every multiplication is a division and every division a multiplication, it is much clearer from the beginning, in this subject, that every composition is a decomposition, and every decomposition a composition. Suppose that P to Q is the ratio compounded of A to B and C to D, and we wish to return back again to the ratio of A to B. We must compound the ratio of P to Q with that of D to C; for it is easily made obvious that the ratios of C to D and D to C compounded give the ratio of a magnitude to itself, the ratio of equality, the use of which effects no alteration.

It is now easy to see that all the operations of algebra which spring from multiplication inclusive, must be represented in geometry by operations of composition, &c. Robert Simson, who, as we have seen, has left a demonstration of the sixth book absolutely unfinished, though "Theon or some unskilful commentator" had provided a lemma which supplied what was wanting, has thought it necessary to add some very complicated propositions on compound ratio at the end of the fifth book. If they were intended as illustrations of the great difficulty of rendering the most common propositions of algebra into geometrical language (and what else could have been meant it is hard to imagine) the algebraical equivalents should have been introduced. Take the proposition K, for instance, which it may safely be asserted no beginner ever fathomed. The following is an arithmetical case of it. If

$$\frac{a}{b}\cdot\frac{c}{d}\cdot\frac{e}{f}\cdot\frac{g}{h} = \frac{i}{k}\cdot\frac{l}{m}\cdot\frac{n}{o}$$

$$\text{And } \frac{a}{b}\cdot\frac{c}{d} = \frac{i}{k}\cdot\frac{l}{m}$$

$$\text{Then } \frac{e}{f}\cdot\frac{g}{h} = \frac{n}{o}$$

RATIONAL. A quantity, algebraic or arithmetical, is rational when it can be expressed without the use of the signs of evolution, such as those of the square root, cube root, &c. [Irrational.]

RATIONALISM is a system of theology, which system began to be developed in Germany during the latter half of the last century. It arose in a great degree as a re-action against the principles and the method of biblical criticism promulgated by Voltaire, Volney, and the French Encyclopaedists. Kant led the way, and his system endeavoured to preserve a medium between infidelity and supernaturalism. He was followed, more or less adopting his system, by Semler, J. D.

Michaelis, and J. G. Eichhorn. They directed their attacks against the deists as well as against the orthodox divines, but they confined the application of the rationalistic principle chiefly to the books of the Old Testament. Semler's principal works in this department are, 'Apparatus ad liberalem Veteris Testamenti Interpretationem,' Halle, 1773; 'Abhandlung von der Untersuchung des Kanons,' 4 vols., Halle, 1771-75, compare Semler's 'Leben, von ihm selbst verfasst,' 2 vols., Halle, 1781-82. The principal works of Michaelis are 'Einleitung in die göttlichen Schriften des alten Bundes,' 2 vols., Göttingen, 1750; 'Mosaisches Recht,' 6 vols., Frankfurt, 1770-75. Eichhorn was by far the most important writer of the school; he laid down and carried out the new principles in his 'Allgemeine Bibliothek der biblischen Literatur,' 10 vols., Leipzig, 1788-1801; 'Einleitung in das Alte Testament,' of which there appeared, in 1824, at Göttingen, the fourth edition, in 5 vols.; 'Einleitung in das Neue Testament,' in 2 vols., and several other works.

Eichhorn, whom we may consider as the representative of the new school, previous to the time when Dr. Paulus began to occupy a prominent position in it, sets out from the principle that the early history of the Jews should be considered in the same light and treated in the same manner as the early history of every other nation; and that a direct interference of the deity in the early affairs of all nations must either be admitted or denied. The reasons which led him to consider the fact of such a direct interference inadmissible in the case of other nations, led him to deny it in the case of the Jews also. Rejecting the views of the deists as unphilosophical and incompatible with the character of early history in general, he proceeds to state that it is natural to all nations in their primitive ages to speak of a divine interference in their affairs, wherever their ignorance conceals from them the real causes of the things which fall within their experience.

It is this belief, according to Eichhorn, which gives a form to all their ideas and expressions. But we, who live in a far more advanced and enlightened age, have neither reason to suppose that any miracles actually took place, nor that any kind of imposition was practised: we have only to translate the expression of those early ages into the language of our own time. In the infancy of mankind everything of which no direct cause appeared was referred to the intervention of supernatural powers; and accordingly all elevated thoughts, great determinations, useful inventions and institutions, and particularly dreams, were considered as the effects of a direct interposition of the deity; extraordinary knowledge and skill were looked upon by the people as proofs of supernatural power and of an intercourse with beings of a higher order. Moreover, not only the people, but the wise and great, were themselves fully convinced that they were acting under the immediate influence and were enjoying the especial favour of the Deity. Taking these premises for granted, and at the same time admitting that the biblical books were written by contemporaries, Eichhorn thought that all the facts of the Mosaic history might be explained as natural occurrences, without supposing, with the deists, that the writer was an impostor. The temptation and the eating of the forbidden fruit, the histories of Noah, Abraham, and Moses, are thus stripped of their supposed allegorical dress and of those features which it is supposed that they have received from the imagination of the writer, and are explained as natural events. According to Eichhorn, Moses was nothing but a great and benevolent patriot, who, after having long entertained the idea of delivering his countrymen from foreign slavery, was suddenly reminded of his scheme in a dream, and believing this dream to be from the deity, he represented it as a summons from Jehovah. The burning and smoking of Mount Sinai, according to this system of exposition, were only the effect of a fire which Moses kindled on the Mount for the purpose of keeping up the excitement of his people; and a storm with lightning, which fortunately happened at the same time, was a useful aid to him. The shining of his face was nothing but the consequence of great heat and excitement, which the lawgiver as well as his people, not knowing the real cause of it, believed to be the effect of a direct interference of the deity.

This system of interpretation was, as we have observed, principally applied to the Old Testament, but the New Testament also contains passages which were too tempting to be passed over by the rationalists. It was at first chiefly the appearance of angels in the New Testament on which Eichhorn tried the rationalistic interpretation, and all passages of this kind ought, according to this critic, to be considered as figurative expressions or allegories: thus a happy chance is represented as a saving angel; an internal joy, as the salutation of an angel; and great calmness and peace of mind, as a comforting angel, &c.

The way being thus prepared, the number of rationalistic divines increased, and their influence became apparent in many other departments of knowledge. A Utilitarian school had at the same time acquired considerable power; and so far as it endeavoured to instruct the people in the so-called useful sciences, and to do away with everything which was deemed superstitious, it went hand in hand with and supported rationalism, which now began to be carried out in its whole extent with regard to the New as well as the Old Testament.

Among the works which gained the greatest popularity, we may mention K. F. Bahrdt, 'Briefe über die Bibel im Volkston,' 1782; Eck, 'Versuch über die Wundergeschichten des Neuen Testaments,' 1795; 'Die Wonder des Neuen Testaments in ihrer wahren Gestalt für ächte Christusverehrer,' 1799; 'Natürliche Geschichte des grossen Propheten von Nazaret,' 1800. The two last works, which were published anonymously, were written by Venturini. Most of these, and the numerous other works of the same tendency, were written in a popular style; and those of Bahrdt had often a coarse and vulgar tone. The philosophical systems of Hegel and Schelling had the same realistic tendency, though in a less popular form. But none of these writers equalled Dr. Paulus of Heidelberg, either in learning or ingenuity; and he it was who most completely developed the whole system of Rationalism. His principal works are—'Philologisch-kritischer und historischer Commentar über das Neue Testament,' 4 vols., Lübeck, 1800–1804 (this work was republished in 1830-33, in 3 vols., with numerous alterations and corrections, under the altered title of 'Exegetisches Handbuch über die drei ersten Evangelien'); 'Das Leben Jesu, als Grundlage zu einer reinen Geschichte des Urchristenthums,' 2 vols., Heidelberg, 1828. Paulus first insists upon the necessity of distinguishing between those passages of the Bible in which the writers simply state facts and those in which they give their own opinions of them. A fact, according to him, is that which the writers describe as having taken place within their own experience; an opinion, on the other hand, is the manner in which they interpret an occurrence and trace it to what they conceive to be its cause. But as these two elements are in most cases interwoven and mixed up with each other in the biblical writings, Paulus conceives it to be the chief object of the biblical critic to separate them, and to discover the genuine historic truth in the various disguises with which the opinions of the age and of the writer have surrounded it; and he thinks with Eichhorn, that this object may be accomplished if the critic transports himself as much as possible to the scene of the events, and supplies such accessory and explanatory circumstances as may have been neglected or overlooked by the reporter or eye-witness. Thus the New as well as the Old Testament is deprived of its divine character, and all supernatural interference in the affairs of the Hebrews and in the introduction and establishment of Christianity is denied. Christ is no longer the son of God, but a wise and virtuous man; his miracles are either acts of friendship and humanity, and manifestations of his skill in the healing art, or the effects of a happy chance. In short, the whole history of the Bible assumes an aspect totally different from that of the original records, and from that which their authors manifestly intended; in fact it becomes a romance without any foundation except the assertion of the Rationalist that things did actually happen thus and thus.

A reaction against the spirit of this school manifested itself during the first ten years of the present century. The dreadful ravages caused by the French Revolution created a general desire to restore or maintain the good old times by returning to the religious and political institutions of past times. But although this reaction was successful in other departments, it had very little effect in theology, as it manifested itself rather in passive and retired mysticism than in energetic efforts against the system of the Rationalists. A vigorous opposition however began in 1810, which was called forth by the publication of Reinhard's 'Geständnisse,' in which Rationalism and Supernaturalism were declared to be diametrically opposed and utterly irreconcilable with each other. This assertion was denied by other theologians, who endeavoured to reconcile the two schools. The contest which then commenced was carried on in a calm and philosophic spirit till 1817, when the centenary anniversary of the Reformation was celebrated in Germany, and the Supernaturalistic party, headed by Dr. Harms, of Kiel, endeavoured to make the question a practical one, and to draw to it the attention of the governments and of the whole German nation. The Rationalists were now universally decried as infidels, and as men who had forfeited all right to be called Christians; and innumerable works were written by the theologians of both parties to defend their opinions. The principal champions on the Supernaturalistic side, besides Harms, were Hengstenberg and Tholuck; on the side of the Rationalists, Gesenius, Wegscheider, Paulus, and Röhr. In these controversies, the rationalistic theory itself almost disappeared, and the question assumed the more general character, whether the Protestant church should allow freedom of thought or not. This turn of the question induced many of the moderate Supernaturalists, who could not sacrifice their liberty of conscience, to side with the Rationalists. Their wish, however, was merely to bring about some kind of a reconciliation, and not to allow the question to become a national one. Their opinion was that it should be kept strictly within scientific limits, and confined to the learned. Although willing to make concessions to the Rationalists on many points, they were anxious to prevent any practical innovations.

Each party, however, continued to maintain its tenets. One of the more important rationalistic works which appeared during this period was 'Was heisst glauben, und wer sind die Unglaübigen?' by David Schuls, 1830; while Neander and Schleiermacher took the opposite side with much learning and success.

Up to the year 1835 this second form of Rationalism had been applied only partially, and chiefly to portions of the Old Testament; but it was then carried out in its full extent with reference to the books of the New Testament, by Dr. David Frederick Strauss, in his 'Das Leben Jesu kritisch bearbeitet,' in 2 vols. The first edition appeared in 1835-36; a second was published in 1837, and a third in 1838. This work, the production of a man of great learning, profound reflection, and critical skill, called forth a host of polemical works, but the best efforts against it were made by the Supernaturalistic school. Rationalism in its first form seems to have received its death-blow from this work and the various controversial writings of Strauss and others, while the new school made rapid progress. The contest between it and the Supernaturalists was however, with few exceptions, conducted in a calm and purely philosophic manner. Both parties were honest enough to give way whenever any of their disputed points were proved to be untenable. This is manifest from the 'Life of Christ' published by Neander, and from the different editions of the work of Strauss.

Notwithstanding the wide breach between the two parties, approximations were made on both sides, so that the Supernaturalists as well as the Rationalists might each be divided into two parties. Some of the latter, such as Paulus, Wegscheider, Gesenius, Schulthess, Schulz, and others, continued to consider reason as their only guide in matters of religion, and rejected every supernatural revelation: others, the so-called Supernaturalistic Rationalists, admitted indeed a supernatural revelation, but considered reason as the only means of recognising and acknowledging it; they thus still allowed reason to be the supreme judge in matters of religion. To this class of Rationalists belong Bretschneider, Von Ammon, Böhme, Hase, Köster, and others. A similar division exists among the Supernaturalists.

The view which the Rationalists had taken of the Scriptures contained some elements which led to a new crisis in German theology. Some parts of the Scriptures, from which the Rationalists, with all their ingenuity, saw no hope of eliciting a genuine history, they had ventured to declare to be a mere legend, tradition, or mythus. This view was gradually applied to a great portion of the Old Testament, as in Bauer's 'Hebräische Mythologie,' Leipzig, 1802. The various and profound investigations into ancient profane history had led to similar results in other departments, and the hollowness of the Rationalist interpretation was either loudly proclaimed or tacitly acknowledged by all parties. The consequence was either a return to the Supernaturalistic view, or further progress in the path which had been opened by the Rationalists themselves. Those Rationalists who could not do the former now applied the principle, to which they had formerly recourse only in cases of extreme difficulty, to the whole body of the early and miraculous portions of the Scriptures, which they placed on the same footing with the early and fabulous stories of ancient Greece and Rome, and considered as a mythical history not written by eye-witnesses or contemporaries, and only recorded after it had been handed down by tradition through many generations. According to this view, all the events in the Bible are either natural events, such as occur in the history of other nations, and which must be examined according to the general principles of historical criticism, or they are of a miraculous and supernatural character, and must for this reason be rejected as not historical, like the fabulous accounts of ancient mythology. As the Rationalistic school directed its first attacks against the deists, so the mythical school, though diametrically opposed to the Supernaturalists, directed its main efforts against Rationalism. We must nevertheless consider this last school as essentially Rationalistic, or as a second form of Rationalism, in as far as, like Rationalism in its first form, it takes reason for its sole guide, and denies all supernatural revelation. The only difference is that it denies the Biblical records to be the works of eye-witnesses and contemporaries, and hence draws the conclusion that it is utterly impossible to elicit from those portions which are supposed to consist of mythical stories anything like a true and connected history.

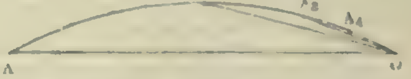
Rationalism in the German sense never made much way in England, being chiefly confined to a portion of the Unitarian sect. But of late years more recent principles of historical and philological evidences, with the incontestable facts established by geological and palæontological investigation, have led to closer though more reverent approaches to it from various quarters. The most remarkable is what is known as the new school of divines at Oxford, of whose views the fullest development is afforded by the works of the late Baden Powell and the Rev. B. Jowett; and the 'Essays and Reviews' issued by these gentlemen, and the Rev. J. Temple, Dr. Williams, Rev. Mr. Wilson, Mr. Goodwin, and Rev. Mr. Pattison, in 1860. The more orthodox view of the question has not been wanting of numerous supporters.

Details of the various opinions of many of the writers mentioned in this article will be found under their respective names in the BIOG. DIV., and under MIRACLES there is given a list of foreign writers, nearly all of whom are purely rationalistic.

RATIOS, PRIME AND ULTIMATE. These terms were first introduced, at least in a system, by Newton, who preferred them to the terms suggested by his own method of fluxions. The first section of the Principia contains the development of their meaning, with various propositions enunciated in their language. In the articles LIMIT and INFINITE we have already had the same notions to consider, couched in different words; but when we remember that the only sure foundation of the differential calculus, that is, of all the higher part of mathematics, must rest upon these notions, it will be worth while to dwell a little upon Newton's form of expression, and his method of employing it. The notions in question actually form part of the knowledge of many persons who are not mathematicians, and all whose occupations lead them to any considerations connected with measurement, must in some degree possess and appeal to them.

All who understand the term ratio must see that the ratio of two quantities does not depend on their actual magnitudes. If one line be to another in the ratio of 3 to 7, the halves, thirds, fourths, &c. of the two lines will have the same ratio; and the subdivision into aliquot parts may be continued without limit; thus the hundred-millionth part of one line will be to the hundred-millionth part of the other as 3 to 7. Ratio then always exists, so long as there is magnitude; but if magnitude should cease to exist, and if both lines should vanish, no idea of ratio can be formed. If however the diminution take place by continual subdivision, this evanescence of magnitude never takes place; for into how many parts soever a line may be divided, each part is a length, still subdivisible for ever.

The consideration here introduced is not an easy one at first, for there is a degree of smallness which evades the senses, and reason must come to their assistance. This makes a great difficulty, for many who think themselves rational geometers are not aware how much of their ordinary perception of geometrical truth is the consequence of what they see, not of what they deduce. All magnitude is relative, so far as the notion of great or small is connected with it; we know this when we stop to think, but we do not easily take it along with us in our thoughts; there is nothing absolutely great or small, but we are continually making an absolute greatness out of magnitude which is great compared with our own bodies, and an absolute smallness of that which is in the same sense comparatively small.



Take AO, an arc of a circle, A_2O its half, A_3O its third part, A_4O its fourth part, and so on; let the chords AO, A_2O, A_3O, &c. be drawn. The points A_1, A_2, A_3, A_4, &c., constitute a series continually approaching to O in position, but never reaching it, for no aliquot part of AO is absolutely nothing. Now it can be shown that A_xO, the chord of (A_xO) the xth part of the arc, will be nearer to a ratio of equality with (A_xO) the greater x is taken, so that any approach to equality may be attained and passed by making x sufficiently great. The beginner's notion is, almost invariably, that two small quantities must be nearly equal, because they are small; and the fallacy under which they proceed is the following:—quantities which are nearly equal to the same are nearly equal to one another; small quantities are all nearly equal to nothing, therefore small quantities are nearly equal to one another. The mistake here lies partly in the use of *nothing* as if it were a quantity, having all the properties of quantity, partly in the supposition that quantities which differ little must be nearly equal. If by differing little be meant that the difference is trifling when compared with the quantities themselves, the notion is a good one: two microscopic animalcules are nearly equal when they differ by a small portion of an animalcule; but if they differ by the size of a gnat, though their absolute difference is still small, compared with our usual standards, the larger is immensely greater than the other. But if the just notion of nearly equal be adopted, it is wrong to say that the chord and arc are nearly equal on account of their smallness, since their small difference may possibly itself be larger than one of them. And as to using *nothing* as a quantity in the fallacious syllogism above given, it must be remembered that, with reference to possibility of subdivision, any quantity, however small, is as distant from nothing as any other quantity, however great, is from infinity.

Nevertheless, as may be rationally shown, the chord and arc are the more nearly equal the smaller they are. The conception of this proposition may be aided as follows:—however small a line may be, we may represent it by as great a number as we please, if we take the unit of measurement still smaller, and sufficiently smaller; now let the arc taken be the nth part of the radius; then if a unit be taken so small that the arc shall be represented by $24n^2$, the chord will be a fractional number extremely near to $24n^2 - 1$. Thus if the arc be one-thousandth of the radius, and a unit be taken to measure it which is its 24-thousandth part, so that the arc is 24,000, the chord will contain that unit a very small fraction more than 23,999 times. And if n be made still greater, the inequality will be made still less, being capable of being made less than a unit out of any number we may name, however great.

In the article LIMIT we should say that the limiting ratio of the arc and chord is unity; in INFINITE, that an infinitely small arc is equal to its chord. Newton's phrase was that the arc and chord are ultimately equal, or that their ultimate ratio is one of equality. He strives to guard this language as much as possible in the Scholium which terminates the first section, and from which we now quote.

"I have premised these lemmas, that I might avoid the tedium of long demonstration, with reductions *ad absurdum*, after the manner of the ancients. Demonstrations are shortened indeed by the method of indivisibles." [CAVALIERI, in BIOG. DIV.] "But since this hypothesis is somewhat difficult, and the method is not thought very geometrical, I have preferred to make what follows depend upon the ultimate sums and ratios of vanishing quantities. . . . . I do not wish to be understood as using indivisibles, but divisible vanishing quantities; not sums and ratios of determinate parts, but limits of sums and ratios. . . "It is objected that there is no ultimate proportion of vanishing quantities, because, before they have vanished the proportion is not ultimate, and after they have vanished there is no proportion. But by the same argument it could equally be contended, that there is no last velocity with which a body reaches the place where its motion stops; for before the body reaches its final position, it has not its last velocity, and when it reaches it, it has no velocity. And the answer is easy: by the last velocity I understand that which the body has, not before it reaches its last point and the motion stops, nor afterwards, but at the moment when it reaches, namely, that very velocity with which the body reaches its last position, and with which the motion ceases. And similarly, by the ultimate ratio of vanishing quantities, is to be understood the ratio of the quantities not before they vanish, nor after they vanish, but with which they vanish. Similarly the prime ratio of nascent quantities is the ratio with which they begin their existence (ratio quacum nascuntur). And the prime and ultimate sum is that with which (whether increasing or diminishing) they begin and cease. . . . It may also be contended, that if the ultimate ratios of vanishing quantities be given, the ultimate magnitudes will be given; and thus that every magnitude will consist of indivisible parts. . . . . But this objection proceeds on a false hypothesis. The ultimate ratios with which quantities vanish are not really the ratios of ultimate quantities, but the limits to which the ratios of quantities diminishing without limit perpetually approach, and which limits may be attained within any given difference, but can never be passed, nor even actually attained, before the quantities are diminished in infinitum. The thing will be more clearly understood by speaking of infinitely great quantities. If two quantities with a given difference be increased in infinitum, the ultimate ratio will be given, that is to say, a ratio of equality, but the ultimate or greatest quantities of which this is the ratio will not therefore be given. In what follows therefore, if ever, thinking of making things more easily conceivable, I should talk of the last possible quantities, or of vanishing or ultimate quantities, do not understand thereby quantities of determinate magnitude, but think always of quantities diminishing without limit."

This notion, whether of limiting ratios, of ultimate ratios, or of the ratios of infinitely small quantities, is a real and positive conception of our minds, but one of which, put it into what language we may, the mode of expression is liable to some objection. The ultimate magnitudes of the senses are not those of the understanding, but all our terms connected with the latter are derived from habits of thought matured by aid of the former. The ultimate arc of a curve which the eyes perceive is, to those eyes, really straight, all curvature being imperceptible. Indeed sensible straightness begins long before length vanishes. Continued reflection only will clear away the approximate truths of the senses, and enable the student to see how the ultimate truths of the theory of limits are to be established.

The study of the theory of ultimate ratios, as given by Newton, is desirable on several grounds. The mere acquisition of the language is a benefit; for subject as all terms in which the propositions can be expressed are to misapprehension, it frequently happens that the associations which one kind of language suggests are corrective of errors which another language has allowed, or even favoured. No student can be sure that his ideas on the subject are sound until, comparing together any proposition (as in Differential Calculus) expressed by means of infinitesimals, limits, and ultimate ratios, the same proposition in the three different ways, he feels a perfect coincidence of meaning between the three statements, and that each expresses as much as, and no more than, the others. Again, the consideration of ultimate ratios puts vividly before the mind of the student who is used to the algebraical methods, a picture of the truth which is meant to be stated, and prevents his resting upon the abstract symbols of the Differential Calculus. For want of such an accompaniment to the latter study, many have found it repulsive, more, unintelligible, at least for a long time, and some have even never arrived at any rational comprehension of its meaning.

RATTANS, or **CANES**, though comparatively unimportant, form a considerable article of commerce in the East. They consist of a kind of palm-reed, which climb over and around the trees in many large and dense forests of the Malayan peninsula and the Eastern Archipelago. They are separated from the trees by a kind of cleaver, and are close, long, well glazed, bright yellow, slender, and supple. They are split into strips and bound into bundles of 100 each. Chinese merchants buy them in Borneo at the extremely low price of about *4d.* per bundle, and sell them largely for use in China. English merchants can obtain about *20d.* per bundle for them at Calcutta. England alone imports as many as 10,000,000 rattans in a year, chiefly for use in chair-bottoms and umbrella-frames.

RAVELIN, a work constructed beyond the main ditch of a fortress, and in front of the curtain between two bastions. It usually consists of two lines of rampart, which meet in a salient angle on a line drawn perpendicular to and bisecting the curtain; and its form on the ground-plan may be seen at Q, *Fig.* 1, Bastion, and at Q Q, Fortification. Its profile, or the figure of a vertical section of its rampart, is similar to that of the enceinte. [Bastion, *Fig.* 2.]

The ravelin was probably first constructed in the place of the more ancient barbacan by the Italian engineers of the 16th century, when, on account of the general employment of cannon in sieges, the ancient towers and walls of masonry were either replaced or covered by ramparts of earth. Its original name, *rivellino*, indicates a derivation from *vegliare*, "to watch;" and both by Maggi (1584) and Errard (1594), rivellino, or ravelin, and bastion, are used as the names of a work beyond the walls of a fortified place. In some cases the rivellino appears to have been merely a parapet of earth covering a small place of arms in which were stationed the men appointed to guard the head of the bridge leading from a postern to the counterscarp of the ditch; and a work of this kind, of a semicircular form, still exists on the exterior of the ditch on one side of Carisbrooke Castle. It can scarcely be doubted that a semicircular form was very frequently adopted for such parapets, and this circumstance may have given rise to the name of demi-lune, or half-moon, by which, even now, the ravelin is often designated. It ought to be observed however that Errard and other writers of that age apply the word ravelin to a work placed immediately in front of the salient angle of a bastion, where the counterscarp of the ditch (which is there in the form of a segment of a circle) constitutes the gorge of the work, and that the name of half-moon may, on this account have been applied to the work, though its faces were retilinear. A work thus situated is now invariably called a counterguard; and the term ravelin, or demi-lune, is confined to the principal outwork in front of the curtain.

When the necessity of increasing the strength of fortresses by means of works beyond the enceinte, in consequence of the superior means employed in the attack, was strongly felt, the ravelin was made more capacious, and was provided with artillery; and, in order to prevent it from being taken by surprise, its ditch was enlarged, and the covered-way was continued on the exterior of the latter along both the faces of the work. Before the middle of the 17th century the ravelins were so small, that the exterior lines (the cordons) of their faces, if produced towards the rear, fell upon the curtain of the enceinte, and the lengths of the faces did not exceed 30 yards. Count Pagan then enlarged the works so that the produced faces fell at the shoulders of the bastions; but Vauban apparently, in what has since been denominated his first system, made the faces of the ravelins about 110 yards long, and directed them towards points on the faces of the bastions at 10 yards from the shoulders [Q, *Fig.* 1, Bastion]. The magnitude of the work was then such as to render it capable of making a good defence: it covered the curtain and flanks of the enceinte, so that the enemy could not demolish their parapets by means of artillery in his distant batteries; and one being placed on each front of the fortress, every two afforded not only a crossing fire on the approaches of the enemy towards the intermediate bastion, but they seriously impeded the formation of the counter-batteries on the crest of the glacis.

It was subsequently perceived that great advantages would arise if the faces of the ravelins were made still longer, and if they were directed to points at a greater distance from the shoulders of the bastions: by the first, as a reverse fire, as it is called, might be directed from the angle of the work upon the enemy's lodgments on the glacis before the bastions, he was compelled to take and make lodgments in two contiguous ravelins before he could proceed to attack the bastion; and by the other, the power of breaching the shoulders of the bastions, that is, in rear of the most advantageous position for a retrenchment, by means of a battery on the glacis, before the salient angle of the ravelin, would be taken away from him. At Landau and other places, Vauban, without increasing the lengths of the faces of the ravelins, directed their exterior lines to points at 20 yards from the shoulders of the bastions; while at Neuf Brisac he not only made the lengths of the faces about 120 yards, but he directed them to points at 30 yards from the shoulders. It should be observed however that at about 20 yards from the counterscarp of the main ditch he changed the directions of the faces, and made the portion between this point and the ditch nearly perpendicular to a line joining the salient angles of the collateral bastions, as in the work Y, Fortification; by which means the second advantage, above mentioned, was lost. The intention of Vauban in thus giving flanks to the ravelin was that he might obtain a fire from thence on any breach formed in the face of the bastion, and that the difficulty of forming a lodgment on the glacis in front of the bastion might be increased so much as to oblige the enemy to take the ravelin before he could execute such lodgment: but experience has shown that this is not the fact; for the flanks, as he has formed them at Neuf Brisac, having no work to cover their prolongations, are enfiladed, and their guns dismounted, at an early period of the siege.

Cormontaingne (1736) greatly improved the ravelin by giving it the figure represented at Q Q, Fortification, making the length of each face about 130 yards, and directing that line to a point between 20 and 30 yards from the shoulders of the bastions. He reduced the terreplein, or space between its parapet and the counterscarp of the redout Y, to 27 feet, in order that the enemy might not find room on it to form batteries for the purpose of breaching the redout of the ravelin; and the faces being unbroken in direction, not only are the shoulders of the bastions covered, but the enemy is prevented from breaching any part between the shoulder and the retrenchment X. The gorge, or rear line, of the ravelin, instead of coinciding with the general direction of the counterscarp of the main ditch, is made parellel to the curtain of the place, in order to take away a part of the terreplein which would have been seen by the enemy from his counter-batteries on the glacis of the bastion. It appears that Cormontaingne wished to give the ravelins a greater length of face than that which has been mentioned, and that he was prevented from doing so through the opposition of his contemporaries. For the advantages to be derived from very salient ravelins, see Fortification.

The only change which has since been made in the position of the ravelin is that which was proposed by Bousmard (1803), and followed in the works executed by order of Napoleon about Alessandria (1807) by Chasseloup de Laubat. It consists in placing the work beyond the glacis of the enceinte, at the foot of which glacis its ditches terminate; the covered-way and glacis before the bastions being continued uninterruptedly along the exterior of the main ditch. It thus becomes impossible to breach the enciente by artillery placed anywhere on the glacis of the ravelin; and, when the direction of each face is broken, as that engineer recommended, the probability of the rampart being enfiladed is much diminished. It might perhaps be objected that the ravelin so detached is liable to be attacked at the gorge; but if the covered-way of the ravelin be made to join that of the collateral bastions, and if its flanks or those of the redout, are disposed so as to allow a fire of musketry to be kept up in the direction by which the enemy must approach the gorge, this danger may be obviated.

The relief of the ravelin, or its elevation above the level of the ground, should be two or three feet less than that of the enceinte, in order that the defenders of the curtain may be able to direct a plunging fire into the work when it is occupied by the enemy. But if in the interior of the ravelin there should be a redout, this last ought, for the same reason, to have less relief by two or three feet than the curtain; and then, in order to afford a plunging fire from the redout into the ravelin, the latter should be two or three feet lower than the former. It ought however to have a command of six or seven feet over the glacis in its front, that the fire of its artillery may not annoy the defenders on the banquette of its covered-way. Therefore, if the command of the enceinte over the ground is 18 feet, and that of the glacis is 7 feet, the differences between the heights of the enceinte and redout, and of the redout and ravelin, may be 2 feet successively.

RAY. [Light.]

RE, in Music, the name given by the Italians and French to the second note of the diatonic scale, and generally throughout Europe to the second of the syllables used in Solmization.

REAL ESTATE. [Property.]

REALGAR. [Arsenic, *Compounds of sulphur and arsenic.*]

REALISTS. [Nominalists.]

REAPING (or cutting corn when it is ripe) is one of the most important operations of harvest. It requires many hands to accomplish it in proper time, so that the corn which is ready for the sickle may not be too ripe and shed, nor the fair weather be allowed to pass before all the corn is secured in barns or stacks. The labourers who are required all the year for the common purposes of husbandry seldom suffice for the harvest, especially on extensive farms, and recourse is usually had to the assistance of mechanics and artisans from the neighbouring towns and villages where the population is considerable, or labourers are induced by good wages to come from a distance. As the harvest is later in those parts of every country which have a more northern situation, or are higher above the level of the sea, bands of reapers from these come to assist in the harvest of those tracts whose produce is earlier. To encourage the annual return of so desirable assistants, every encouragement is given them, not only by wages, but also by food and drink, and amusements after the toil of the day. Thus the time of harvest is a time of rejoicing both to the labourers and the master.

The common reaping-hook, or sickle, with which the corn is usually cut, is one of the oldest instruments of husbandry; and the goddess Ceres was generally represented by the ancients with a sheaf of corn and sickle in her hand. In reaping with the sickle, a portion of the stems is collected with the left hand, and held fast; while the sickle in the right hand is inserted below the left, taking the stems in its semicircular blade, and cutting them through by drawing the sickle so as to act as a saw, for which purpose the edge is finely serrated in a direction from the point to the handle. The heads of the corn, with the upper part of the straw, are then laid on the ground in quantities which may readily be collected into a sheaf. Practice soon gives dexterity to the reaper; and he finds it more expeditious to cut small quantities in succession until he has filled his hand, than to attempt to cut through a large handful at once. Severe wounds are often inflicted on the fingers of the left hand by beginners, even to the loss of a finger; but this soon makes them cautious and expert. The division of labour is introduced with advantage amongst a band of reapers. A certain number cut the corn, while others follow to gather the sheaves; some only preparing the bands, and others tying them and setting up the sheaves into stooks or shocks, which usually consist of ten or twelve sheaves. The smaller the sheaves are, the less injury the corn sustains in a wet harvest; as the moisture in a thick sheaf does not so readily evaporate. Hence it is the interest of the farmer to see that the reapers do not make the sheaves too large. In many places there is a regular measure for the circumference of a sheaf, which should never exceed thirty inches. The bands are made by taking two small handfuls of the cut corn, and crossing them just below the ears into a knot. The sheaf is then pressed with the knee, and the band drawn tightly around it. The ends are twisted together like a rope, and inserted under the band, which effectually fastens it. This operation is soon learnt, and is done very rapidly. The sheaves should be so tied that there may be no danger of their falling loose when pitched into the cart or stacked, without being so tight as to prevent the moisture in the straw from evaporating. They should not be tied too near the ears, but rather nearer to the butt. The sheaves, when tied, are placed two and two on the butt-ends, with the ears leaning against each other: sometimes they are placed in a circle, all the ears being together, and the buts slanting outwards; a sheaf is then opened, by inserting the hand into the middle of the ears, and reversed over the tops of the preceding, forming a cone, and covering all the other ears, while it hangs down around them. In this position they will bear much rain without injury. It is a good practice to place the shocks across the furrows between the stitches or lands, so as to allow the air to circulate more freely around them. In this case four or five sheaves are placed in a row, leaning against as many in a parallel row; and two sheaves, being opened, are reversed over them to protect the ears. Whatever be the mode adopted in reaping the corn, the same kind of sheaves are formed, and set up in shocks.

Wherever the sickle is used for reaping, the straw is cut at a certain height from the ground, and the remainder forms a long stubble, which is usually mown at leisure after harvest, and carried into the yard for litter; but in the neighbourhood of large towns, where straw is sold at a good price, or exchanged for stable dung, it is important that as much as possible of it should be cut with the corn. This has introduced the practice called fagging, and sometimes bagging, the origin of which provincial expression is not well known. The instrument used for this purpose partakes of the nature of a scythe, as well as of a reaping-hook. It is shaped like a sickle, but is much larger and broader; and instead of being indented like a saw, it has a sharp edge like a scythe, which is renewed when blunt by means of a stone or bat. The fagging-hook cuts the straw close to the ground by a stroke of the hand; and its curved form is only useful in collecting stray stems, and holding a certain quantity of them between it and the left hand of the reaper when he makes up a sheaf. A certain quantity is cut towards the standing corn, the left hand pressing it down at the same time. When as much is thus cut as would make half a small sheaf, the reaper comes backwards, cutting in a direction at right angles to the first, and rolling together the two parts, which he carries in the bend of his hook and places on the band which has been prepared for him. A full-sized sheaf is usually composed of two cuttings. Two men will fully employ a third to make bands for them, tie up the sheaves, and set them up. This method of reaping is laborious, on account of the stooping required to cut near the ground. The Hainault scythe, which has been described in most agricultural works, does the work better, and with less fatigue. It is in fact a fagging-hook, not quite so curved, of which the handle is longer, and placed at an angle with the plane of the blade. It requires some practice to give the proper swing to it by a peculiar motion of the wrist; but when this is once acquired, a considerable saving of labour and time is effected. Many attempts have been made to bring it into use in England; but, from the obstinacy of the labourers, or the want of perseverance in the masters, without much success. A better instrument, however, on extensive farms, is the cradle-scythe, which, in the hands of an expert mower, will do more work and more effectually secure all the straw than any other instrument.

The objection to the great barn-room required for so much straw is obviated by the practice of stacking the corn in the open air, on proper stands to keep it dry and out of the reach of vermin. The additional trouble in threshing is not so great as that of mowing or raking the stubble, which is generally deferred till half of it is lost by decomposition by the air and moisture. When the saving of time is considered as well as the saving of expense, there seems to be no doubt that on an extensive farm the scythe is far preferable to the sickle for cutting every kind of grain. Barley and oats are usually mown and carried without tying them into sheaves, but this is a slovenly and wasteful practice: by means of the cradle-scythe they may be mown so regularly as to be readily tied into sheaves; and the additional expense will be fully compensated by the saving of all the corn which, being on the outside of the stack, is lost by the depredations of small birds.

Beans are usually reaped by the sickle, the stems being too strong and too wide apart to admit of the scythe. Where it can be done conveniently, without the soil adhering too much to the roots, it is better to pull them up, and tie them in bundles with straw bands, or tar-twine, which will be found both a convenient and economical method.

Peas are generally reaped by means of two large hooks similar to the fagging-hooks, one of which is held in each hand; and the stems, which are generally much interwoven, are partly cut and partly torn from the roots, and so rolled up into a small bundle laid loose in order that it may dry. Tares are reaped in the same way.

The expense of reaping corn is considerable, especially where the population is scanty. In the eastern counties men are engaged for the whole harvest, which, in favourable weather, is supposed to be completed in a month. During this time they have their usual daily wages, with or without food, and a certain sum besides, as harvest money. In other districts the labourers reap the corn by the acre, with a certain allowance of beer, or money instead of it. The price of fagging in Middlesex and within 30 miles around London varies from nine to twelve shillings per acre, according to the crop, and if it is lodged, as much as fifteen shillings is often paid, including beer. The use of the scythe considerably diminishes the expense, as fewer labourers are required.

There have been many attempts to introduce machinery for reaping corn; and within the past ten years the principle of the reaping-machine, invented by the Rev. Mr. Bell, of Forfarshire, a quarter of a century ago, and since successfully carried out in the United States of America, has been largely applied by many makers on both sides of the Atlantic, and we have now ten or twelve different reaping-machines, more or less differing from Bell's reaper, in successful operation. Many thousands of such machines are now at work in this country, and effect a great saving both of time and money at harvest time. Crosskill, of Beverley, manufactures Bell's reaper; Burgess & Key, of Newgate-street, manufacture M'Cormick's reaper, in which a serrated edge, oscillating in front of the corn, cuts it and lays it on a traversing screw platform, by which, as in Bell's, it is carried aside and laid in swathes on the ground. Cuthbert, of Bedal, and many others, manufacture a smaller machine, in which the corn is delivered from the platform on which it falls by a man who rides on the machine. All these machines are in extensive and successful use.

REASON, according to the common notion, is the highest faculty of the human mind, by which man is distinguished from brutes, and which enables him to contemplate things spiritual as well as material, to weigh all that can be said or thought for and against them, and hence to draw conclusions, and to act accordingly. A man may therefore be said to possess reason in proportion as he actually exercises that power, that is, reasons and acts according to the conclusions or results at which he has arrived. In such expressions as "We have reason to believe such an account," or "He has no reason to be dissatisfied," the word "reason" does not signify the mental power itself, but the conclusion or result of the process of reasoning, in contradistinction to motives, which are never the results of mental operations, but merely outward circumstances by which our actions are influenced.

Thus far reason is of a purely practical nature, and Kant therefore divided reason (if we may venture to translate his word *Vernunft* by the English word *reason*) into practical and theoretical. The latter, which is also called pure, ideal, or transcendental reason, is, according to him, the mind's power of producing ideas *à priori* from its own resources, or the power of conceiving things and their attributes which lie beyond the sphere of our experience, such as infinity, the absolute, God, the supreme good, &c. How far our knowledge of these things can extend is shown in the work of Kant, entitled 'Kritik der reinen Vernunft,' or 'Criticism of Pure Reason.' Reason, in its practical acceptation, forms ideas *à posteriori*, in as far as it derives them from a consideration and comparison of the phenomena of the external world, endeavours to discover unity in variety, and traces all phenomena to one source, a supreme reason, of which human reason is only a reflex.

Schelling defines reason to be the identity of the subjective and the objective, that is, the identity of the power which knows and that which it knows, which includes the knowledge of this identity. As the original identity, says he, exists in God, or is God, reason is a direct knowledge or an intellectual perception of God, of whom no indirect knowledge is possible. Hence God and reason are essentially of the same nature; they are identical: God is in reason, and reason is in God.

(G. M. Klein, *Beiträge zum Studien der Philosophie als Wissenschaft des All.* There are some good remarks on this subject in S. T. Coleridge's *Aids to Reflection.*)

REBATE. [Discount.]

REBEC (*Rebec*, Fr.), a musical instrument of the violin kind, which had three strings tuned in fifths, played on by a bow. This, which has long been in disuse, was small in size, something between the modern violin and the dancing-master's *kit*, or pocket-fiddle, and seems to have been the primitive violin. Laborde says that it was the favourite instrument of the minstrels; and the *ribible*, of which Chaucer and Gower speak, is supposed to have been the rebec. It was much used at festive entertainments. Milton, in *L'Allegro*, mentions it as the "jocund rebec."

REBELLION. [Sovereignty.]

REBUTTER. [Pleading.]

RECAPTION. [Replevin.]

RECAPTURE. [Prize.]

RECEIPT, a written discharge of a debtor on the payment of money due. When given for sums greater than two pounds, it must be stamped. Though evidence of payment, it is not absolute proof, and may accordingly be rebutted by showing that it has been given under mistake, or obtained by fraud.

RECEIVER. A receiver is a person appointed by the Court of Chancery to receive the rents and profits of land, or the produce of other property, which is in dispute in a cause in that court. He is an officer or agent of the court, and as such under its general control.

A receiver is never appointed unless a suit is pending concerning the property in question; and he is usually appointed upon motion in court, after notice has been given to the proper parties. The motion is generally made after answer; under special circumstances it may be made before answer, but the motion must be supported by sufficient affidavits. The cases in which a receiver is appointed are those in which there is great danger of property being wasted or lost, owing to the want of a proper person to look after it. The following are some instances in which a receiver will be appointed: when an infant is entitled to real estate, especially if it be of considerable magnitude: in suits between partners in trade for the purpose of winding up the concern, when a partner is grossly misconducting himself, disposing of the partnership property, or excluding his copartners from the management of the partnership affairs: when there is danger of the assets of a testator being lost or wasted through the misconduct of an executor. A manager of West India estates has power to set and let them, and to expend money in repairs; but a receiver has not such power, except as hereafter mentioned.

Certain persons are disqualified from being receivers, such as a solicitor in the cause, the next friend of the infant plaintiff, a peer of the realm, and a receiver-general of a county. The receiver must give security, according to the value of the property of which he is appointed receiver.

It is the duty of the receiver, when his appointment is completed, to inform the tenants of the estate in question of his appointment, that they may pay the rents to him.

A receiver is paid by a per centage on the sum which he receives, usually a shilling in the pound; and sometimes, in the case of large estates, by a fixed salary. He must annually pass his accounts of receipts and payments. It is usually directed in the order or decree for the appointment of a receiver, that the receiver shall from time to time pay the balances which shall be due from him into the Bank, with the privity of the Accountant-General, to the credit of the cause. A receiver who does not pass his accounts and pay in the balances may be deprived of his salary. (15 Ve. 273.) If he make default in payment of his balances, the recognizances may be put in suit. A receiver of rents and profits has to pass yearly or half-yearly accounts, as the rents and profits are received, and he is chargeable with interest at 5 per cent. on balances in his hands which he neglects to pay at the times fixed for that purpose.

When the receiver has passed his final account, and paid the balance into the Bank, or to the person entitled to receive the money, to whom the order directs him to pay it, he may apply by petition to the court for the vacating of the recognizances and his own discharge, and an order will be made accordingly, upon all the facts being proved to the court, which are the foundation of the receiver's right to his discharge. A receiver is not liable to make good unavoidable losses.

RECEIVER. [Distillation; Retort.]

RECIPROCAL, a mathematical term mostly applied to the fraction made by inverting another fraction; thus $\frac{8}{7}$ is the reciprocal of $\frac{7}{8}$, and $\frac{1}{7}$ of 7 or $\frac{7}{1}$. The term arises from the common meaning of the adjective reciprocal, and would be properly applied in every case in which A has to B the same sort of relation that B has to A. Custom however confines the absolute use of the term to that above-mentioned. A reciprocal property is one which each of two things has with reference to the other; thus if A and B be what are called conjugate diameters of a conic section, the tangent at either extremity of A is parallel to B, and that at either extremity of B is parallel to A. Hence these lines are reciprocally connected with each other, and are therefore called conjugate; for the word conjugate, which denotes joined, generally means joined by a reciprocal property.

RECITATIVE (*Recitativo*, It.), language delivered in musical tones, that is, in the sounds of the musical scale. It differs from the air in having no fixed time or measure, the lengths of the notes depending on the singer, who regulates them according to his own notion of the emphasis and expression required; and it is not governed by any principal or predominant key, though its final cadence or close must be in some cognate key of the air which follows, or, at least, in no very remote key. Recitative is of two kinds—*Unaccompanied* and *Accompanied*. The first is when a few occasional chords are struck by the piano-forte, or by a violoncello, to give the singer the pitch, and intimate to him the harmony. The second is when all, or a considerable portion, of the instruments in the orchestra accompany the singer, either in sustained chords or in florid passages, as the composer may deem expedient, in order to give the true expression or colouring to the passion or sentiment to be expressed. Perhaps the Italian definition of recitative, *musica parlante*—speaking music—is the best, as it certainly is the most concise, that can be offered.

There can be no doubt that the language of the ancient drama, both Greek and Roman, was delivered in a kind of recitative. [Music; Opera.]

RECKONING AT SEA is the process of computing the several elements which relate to the determination of the ship's place at any time. The term may include the operations which are performed in finding the latitude and longitude of the ship, the variation of the the needle, &c., from celestial observations; and the part which is independent of these is called the *dead-reckoning*. It is this last only which we purpose here to explain.

When a ship crosses the seas towards the place of its destination, its path, on account of the various winds, currents, &c., by which it is impelled, is always indirect, and generally consists of numerous zig-zags, whose portions are lines of a few miles in length. The length of each of these lines, and the angle which it makes with the terrestrial meridian passing through one of its extremities (all necessary corrections having been made) are the data obtained by the *log-line* and *compass;* and the earth being supposed to be a sphere, those lines might be considered as arcs of great circles. Hence the rules of spherical trigonometry might be employed to find the length of an arc joining the two extremities of the series of indirect lines, and the angle which it makes with the meridian passing through either of those extremities; and, from these, the geographical position of the ship. But, because this process is considered laborious, others possessing greater facilities are, according to circumstances, employed, and these will be described after it has been shown what are the corrections which the observed elements require before they can be used in the computations.

The reckoning may be said to commence when the ship is on the point of quitting a harbour or road; and the first circumstances to be recorded are the observed bearing and the estimated distance of some remarkable object on the coast whose geographical position is known, together with the bearing of the ship's line of motion at the time, and her velocity on that line.

Let it be here observed that the said object on the coast is called the point of *departure*, and that the angle which the line of a ship's motion at any time makes with the meridian passing through the actual position of the ship is called her *course*. Now, while the angle indicated by the compass remains the same, the ship's path, except when it coincides with the meridian, or with a line tending due east and west, is a portion of that which is called the *loxodromic curve* [RHUMB-LINE]; yet, to the extent of a few miles, it is the custom to consider it as a right line, and, therefore, as making a constant angle with the meridian passing through one of its extremities. The deviation of the magnetic from the true meridian (the declination or variation of the needle) differing in different places, the amount of that variation (ascertained by celestial observations as often as possible) must be added to or subtracted from the angles observed with the compass, in order to have the bearing, or course, from the true meridian. But while a ship is sailing with the wind in a direction oblique to the line of her keel, she is compelled, by the force of the wind and the resistance of the water against her side, to move in the direction of a line which makes some angle with her keel on the side opposite to that from which the wind is blowing; this angle is called the *lee-way*, and as it differs for different ships, it must always be determined by trial in some one of the ways proposed in treatises on navigation. The estimated amount of the lee-way is a second correction, which must be applied to the course observed with the compass, in order to obtain the correct angle with the meridian.

The velocity of the ship is ascertained by means of the log line [LOG-LINE], which at once indicates the number of geographical miles (equatorial minutes) she has passed over in an hour; and consequently, supposing her motion to be uniform, the space through which the ship has sailed on a particular course in a given number of hours is known. This is technically called the *distance*.

Again, when a ship is sailing either in a current of the ocean, or in a tide near a shore, her velocity and the direction of her motion will be affected by those of the current or tide. First, if the ship is impelled by the wind in the same direction as the current is moving, it is evident that the velocity given by the log will be only the difference between the ship's real velocity and that of the current, and consequently the latter must be added to the velocity given by the log in order to have the true velocity. On the other hand, if the ship is impelled by the wind in a direction contrary to that of the current, the velocity of the latter must be subtracted from that given by the log, in order to obtain the true velocity of the ship. Again, if the direction of the current is oblique to the line of the ship's motion according to the compass, the true path and velocity of the ship will, by the *composition of motions*, be the diagonal of a parallelogram formed on lines representing the observed directions and velocities of the ship and current; consequently, since this rule is the same as that by which is found a path of the ship which shall be equivalent in length and direction to any two successive paths whose lengths and directions are given, it is evident that among the registered courses and velocities of a ship it will be only necessary to insert the observed direction and velocity of the current, as if the ship had actually moved in that direction, and with that velocity during the time that she continued to sail in the current. The like remark may be made respecting the deviation of a ship from the course on which she appears by the compass to have sailed, in consequence of a swell of the sea, by which she may be driven in some other direction. This direction must be observed, and the velocity estimated according to the judgment of the seaman.

Now, in order to show how all the corrections may be applied to the observed elements, let it be supposed that at the noon of some day a remarkable object A on the shore was observed by the compass to bear W. by N., and that its estimated distance from the ship was 20 miles. At the same moment let the ship begin to sail on a course which is S.W. by the compass; and let the velocity by the log be 3 knots, or 3 miles per hour. Also let the following table express the several memoranda in the order in which they may be supposed to have been made in the course of one day; that is, according to the practice of seamen, between the noon of one day and the noon of the next.

The bearing of the ship from the point of departure being corrected for the variation of the needle becomes N. 78° 15′ E.; the distance is 20 miles.

Day of Month.	Hour.	Knots.	Wind.	Course.	Lee-way.	Remarks.
	Noon.	3	W.N.W.	S.W. (or S. 45° W.)	0.	The point A of departure bore W. by N., distant 20 miles; its lat. ——, and long. ——.
	2 P.M.	4½				
	8	5¼				
	10	6	W. by N.	S.E. by S. (or S. 33° 45′ E.)	¼ E., or 2° 49′ E.	A swell setting towards E.N.E. from 2 P.M. to 8 P.M.: velocity 6 miles per hour.
	12	4½				
	6 A.M.	5¾				
	8	6	W.	S.S.W. (or S. 22° 30′ W.)	1 E., or 11° 15′ E.	A current setting towards S.S.E. from 10 A.M. to 10 P.M.: velocity 2 miles per hour. Variation N. 24° W.
	10	6½				

The first course corrected in like manner becomes S. 21° W.; and the distance run between noon and 10 P.M. is 43·5 miles.

The third course corrected for lee-way and variation becomes S. 60° 34′ E.; and the distance run between 10 P.M. and 8 A.M. is 50·5 miles.

The fourth course corrected in like manner becomes S. 12° 45′ E.; and the distance run between 8 A.M. and noon is 25 miles.

The direction of the swell corrected for the variation of the needle becomes N. 43° 30′ E.; and the distance is 36 miles. Lastly, the direction of the current corrected also for the variation becomes S. 46° 30′ E.; and the distance is 24 miles.

These corrected courses and distances are then inserted in order, as in the first and second columns of the following table:—

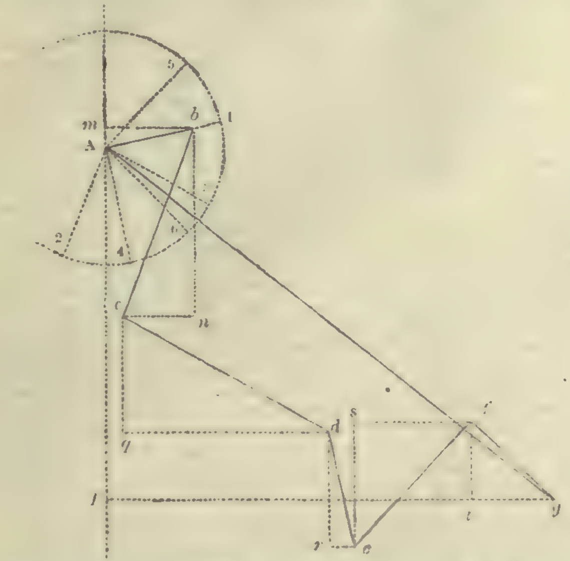
Courses.	Distances.	N.	S.	E.	W.
N. 78° 15′ E.	20	4·07 (=Am)	. . .	19·58 (=*bm*)	. . .
S. 21° W.	43·5	. . .	40·7 (=*bn*)	. . .	15·59 (=*cn*)
S. 60° 34′ E.	50·5	. . .	24·82 (=*cq*)	43·98 (=*dq*)	. . .
S. 12° 45′ E.	25	. . .	24·38 (=*dr*)	5·52 (=*re*)	. . .
N. 43° 30′ E.	36	26·11 (=*se*)	. . .	24·78 (=*sf*)	. . .
S. 46° 30′ E.	24	. . .	16·52 (=*ft*)	17·41 (=*gt*)	. . .

Now, if the navigation is comprehended within about ten degrees on each side of the equator, such a zone of the earth may be supposed to be projected on the interior surface of a circumscribing cylinder, and then developed on a plane; in which state the meridians and the parallels of latitude become right lines parallel to themselves respectively, and the length of a degree of longitude on every parallel equal to that of a degree on the equator or on the meridians. This is called the *plane chart*, and the projection of a ship's path on it is called *plane sailing*.

Let the several directions in which the ship has moved, and the distances passed over in each direction, be represented in the subjoined diagram, the construction of which, agreeably to the nature of the plane chart, is as follows:—

Draw the lines A 1, A 2, A 3, &c., making with A*p*, the meridian of the point of departure, angles equal to the several courses as they occur successively in the preceding table (col. 1), and draw the lines *bc*, *cd*, &c., parallel to A 2, A 3, &c., respectively; the distances A*b*, *bc*, *cd*, &c., being laid down according to the successive numbers in col. 2 by a scale of equal parts representing geographical miles (or equatorial minutes). At the end of the day the ship is arrived at the point *g*;

therefore if A and *g* be joined, and *gp* be drawn perpendicularly to A*p*, the angle *p*A*g* is the resulting course, A*g* the resulting distance, A*p* the difference of latitude between A and *g*, and *pg* is what is called the *departure*, which, in plane sailing, is identical with the difference of longitude between the same points A and *g*.



By drawing lines perpendicular and parallel to A*p*, as in the above diagram, there will be formed the several right-angled plane triangles A*bm*, *bcn*, &c., in each of which there are given the hypothenuse and the angles; and consequently by the rules of plane trigonometry the several sides A*m*, *bm*, *cn*, *bn*, &c., may be computed. Now, let these computed values be placed in the third and succeeding columns of the above table in the following order:—those which are parallel to A*p* in the column N. or S., according as the lines which represent them lie towards the north or towards the south of that extremity which is first, in order of sailing, on the corresponding hypothenuse; and those which are perpendicular to A*p* in the column E. or W., according as the lines which represent them lie towards the east or west of that same extremity. Then the sum of the numbers in the column N. being subtracted from the sum of those in S. will be found to leave 76·24, and this will be the value of A*p* in geographical miles (or equatorial minutes); consequently 1° 16′ 14″ will express the extent in latitude to which, on the whole, the ship has sailed southwards during the day. Again the number in W. being subtracted from the sum of those in E. will leave 95·68 (= 1° 35′ 41″), and this will be the value of *pg*, or the extent in longitude which, on the whole, the ship has sailed eastward during the day. Thus the position of A being known, we have that of *g*. In the right-angled plane triangle A*pg*, having A*p* and *pg* in miles, as above, we may compute A*g* and the angle *p*A*g*, that is, the resulting distance and course. The former will be found to be = 122·35 miles, and the latter S. 51° 27′ E. The series of zig-zag lines which a ship may describe is called a *traverse;* the preceding table is called a *traverse table*, and the whole operation of finding the resulting course and distance is called *traverse sailing*.

In practice, both the construction and calculation above indicated are superseded by the use of the table of *difference of latitude* and *departure*, which is given in treatises on navigation, and is called a traverse table. The numbers in the table are nothing more than the computed values of the sides of right-angled triangles; the hypothenuse, or the distance, and the adjacent angle, or the course, being given. Thus, by referring to such a table, the courses and distances being used as arguments, the numbers in the columns N. S. E. W. above, might have been found sufficiently near the truth. And, conversely, seeking in the table the difference of latitude (= 76) and the departure (= 96), the corresponding distance (= 122) would be seen in its proper column, and the angle or course (= 51°) at the bottom of the page.

The logarithmic or Gunter's scale [SCALE] was formerly, for the sake of expedition, much used in the resolution both of plain and spherical triangles for the purposes of navigation. If, for example, it were required by that instrument to find the values of *cq* and *qd* in the triangle *cqd*, the following proportions

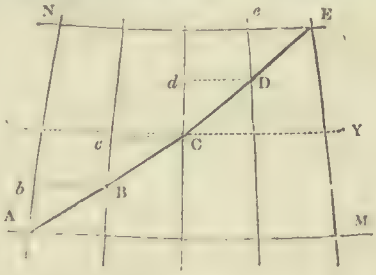
$$\text{Rad.} : \sin.\, qcd\ (60^\circ\ 34') :: cd\ (50{\cdot}5) : qd\ (=44)$$
$$\text{Rad.} : \sin.\, cdq\ (29^\circ\ 26') :: cd : cq\ (=25)$$

might be worked by taking in the compasses the distance from 90° to 60° 34′ on the line of sines, and applying that distance on the line of numbers from 50·5 towards zero; the other foot of the compasses would fall on 44, which is the value of *qd*; again by taking the distance from 90° to 29° 26′ on the line of sines, and applying it on the line of numbers, from 50·5, as before, the other foot of the compasses would fall on 25, which is the value of *cq*. But it is evident that when the angle is small, or nearly a right angle, the instrument must be very inaccurate.

Should a ship, on any part of the earth's surface, sail for a short time in a direction either due east or due west, so that during that time it might be considered, without sensible error, as sailing on the circumference of a parallel of latitude, the determination of its place is obtained by a different process. Thus, the earth being supposed to be a sphere, the length, in miles, of any arc of the equator between the meridian circles passing through its extremities is to the length, in miles, of the arc between the same meridians on any given parallel of latitude as radius is to the cosine of the latitude of the parallel. Therefore, when the number of geographical miles passed over on any parallel of latitude is known by the log (all due corrections being supposed to be made), the difference of longitude corresponding to that distance may be found at once by the above proportion. Evidently also, if any three whatever of the terms are given, the fourth can be found; and thus every variation of the case may be resolved. This is called *parallel sailing*.

But the tables of difference of latitude and departure may be rendered available for finding the required term if we consider the latitude of the parallel on which the ship is sailing to represent what is called the *course* in those tables; the distance in miles on the parallel as the *difference of latitude*, and the difference of longitude in geographical miles as the *distance* in the tables; and then, by inspection as before, the required term may be found.

The third method of operating, which is called *middle latitude sailing*, has been defined under LONGITUDE AND LATITUDE, METHODS OF FINDING, and we have here only to point out its application. Let A E be a portion of the rhumb-line which a ship describes while her motion continues to coincide with the direction of one point of the compass, that is to say, while it makes a constant angle with the meridians of her successive places. Let this curve be divided into any parts, A B, B C, &c., of small extent, so that each part may, without sensible error, be considered as a straight line; and imagine both meridians and parallels of latitude to be drawn through A, B, C, &c. Then the several triangles B A *b*, C B *c*, &c., being considered as plane triangles, if the constant angle B A *b*, C B *c*, &c., be represented by A, we shall have—



$$AB \cos. A = Ab\ ,\ BC \cos. A = Bc\ ,\ \&c.;\ \text{also}$$
$$AB \sin. A = Bb\ ,\ BC \sin. A = Cc\ ,\ \&c.;\ \text{whence, by addition,—}$$
$$(AB + BC + \&c.) \cos. A = Ab + Bc + \&c.,\ \text{and}$$
$$(AB + BC + \&c.) \sin. A = Bb + Cc + \&c.$$

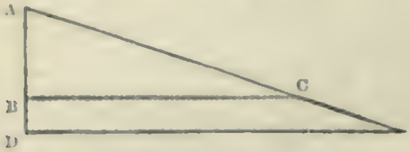
It is evident therefore that the sum of all the distances multiplied by the cosine of the course will be equal to E M, the difference between the latitudes of A and E as in plane sailing; but the sum of all the distances multiplied by the sine of the course (that is, the sum of all the departures, B *b*, C *c*, &c.) will be less than A M and greater than N E. Therefore, as an approximation to the truth, we may consider the sum of all these departures as the length, in miles, of the arc X Y (between A N and M E) of a parallel of latitude equally distant from A M and N E; that is, of a parallel whose latitude is an arithmetical mean between the latitudes of A and E. Consequently, as in the theorem for parallel sailing, the difference between the longitudes of A and E will be obtained from the proportion

$$\text{Cos. } \textit{mid. lat.}\ (=\text{lat. of } XY) : \text{Rad.} :: (AB + BC + \&c.) \sin. A : \text{diff. of long.};$$

and, instead of working the proportion, the tables of difference of latitude and departure may be used as before.

If we imagine the earth's surface to be developed on a plane so that the meridians and parallels of latitude may be respectively parallel to themselves as in the plane chart; and if the lengths of infinitely small portions of the circumference of the equator have to the lengths of corresponding portions of a meridian, in any latitude, the ratio that the radius bears to the secant of that latitude [MERCATOR'S PROJECTION; RHUMB-LINE], there may be formed a species of chart which will afford a general and at the same time a sufficiently easy method of determining the elements relating to a ship's place. This method is called *Mercator's sailing*. In the chart just alluded to, the length of a degree, minute, &c., of longitude, on any parallel of latitude, is constant, being the same as the length on the equator, on account of the parallelism of the meridians; but, in any latitude, the length of a small meridional arc (which, without sensible error, may be of one minute) varying with the secant of the latitude of the arc, the distance, on the map, of any parallel of latitude from the equator will be equal to the sum of the secants of all the minutes in the degrees, &c., expressing the latitude of the parallel. Now, in the tables of *meridional parts* which are given in treatises on navigation, the numbers under the arguments 1 min., 2 min., 3 min., &c., express the values of such sums of secants, the length of an equatorial minute (or geographical mile) being unity. Hence the difference between the numbers, in the table, corresponding to the latitudes of two given points, will express the number of such minutes or miles on the map between these points.

By the help of this table a triangle may be always constructed with the data of the problem; and the terms required may be obtained by measurement. In the subjoined figure, let A D be the direction of the meridian passing through the ship at A, and B A C be her course; then, if A C be made equal to the distance in miles by a scale of equal parts, and B C be drawn perpendicular to A D, A B and B C measured on the same scale will be the difference of latitude and departure as in plane sailing. Now, if A D be made, by the same scale, equal to the difference between the meridional parts which, in the table, correspond to the latitudes of the point A and C, and D E be drawn parallel to B C, D E on the same scale will express, in miles or minutes, the true difference between the longitudes of A and C.



What has been said may serve as an example of the manner of constructing the triangle, when the course, the distance, and the latitudes of the two extremities of the distance-line are given, and it is required to find the difference between the longitudes of those extremities. Again, let the ship's course and distance from any point A, and also the latitude of that point, be given, to find the differences both of longitude and latitude. The formation of the triangle A B C is the same as that just mentioned, and A B being measured on the scale of equal parts is the true difference of latitude (in miles or minutes); this being added to or subtracted from the latitude of A, gives the latitude of C. Then, with these latitudes find from the table the difference between the meridional parts, and proceed as before to find the difference of longitude. If the latitudes of the ship at two places were given, and also the distance between those places, and it were required to find the course and the difference of longitude:—on the meridian line passing through one of the places A, make A B equal to the difference of latitude in miles by the scale of equal parts, and make A D by the same scale equal to the difference between the meridional parts, in the table, corresponding to the latitudes; then draw the indefinite perpendiculars B C and D E, and from A as a centre with a radius equal to the given distance describe an arc intersecting B C in C. Join A and C, and produce the line to E; then ∠ B A C will be the course, and D E, measured as before, the difference of longitude.

It is easy to perceive that the table of differences of latitude and departures may be used in Mercator's sailing in the same way as it would be employed in plane sailing, if the meridional difference of the latitudes, from the table of meridional parts, be made to hold the place of the simple difference of latitude. Thus, in the second of the above examples, with the given course and distance, find by inspection in the first-mentioned table the difference of latitude; then, having got by addition or subtraction the latitude of the place at which the ship is arrived find in the table of meridional parts the numbers corresponding to those latitudes, and take their difference. Lastly, with this difference, as a simple difference of latitude, and with the course, find the departure by inspection in the first table; this departure is the required difference of longitude.

When a ship is in a high latitude, it is necessary to determine the difference of longitude, either by middle latitude or by Mercator's sailing, for every particular course on which the ship may have sailed.

The daily differences of latitude and longitude being thus obtained, the seaman knows, within the degree of accuracy of which his data admit, the latitude and longitude of the ship on any day; but it is easy to perceive that the uncertainties respecting the estimates of the distances run, the variations of the needle, the effects produced by currents, &c., must, in time, render the results of the reckoning very erroneous; and therefore it is of the utmost importance to correct them frequently by celestial observations. The determination of the latitude by meridional or other altitudes is easy; and that of the longitude by lunar distances or by chronometers should be made as often as possible. Every geographical position thus determined with precision serves, by comparison with the results of the dead-reckoning, to lead to a knowledge of the causes of the errors which exist in the latter, and becomes a point of departure for the next succeeding portion of the voyage.

RECOGNISANCE is an obligation of record, entered into before some court of record, or magistrate duly authorised, by which the party entering into it (the cognisor), whose signature is not necessary, acknowledges (recognises) that he owes a sum of money to the queen, or to some private individual, who is called the cognisee. This sum is named the amount of the recognisance. The acknowledgment is generally followed by an undertaking on the part of the cognisor to do some act, such as to keep the peace, to pay a sum of money, to attend to give evidence, &c. On the performance of this act, the cognisor is discharged from his recognisance. On his default, the recognisance is forfeited, and he becomes indebted absolutely to the amount of the recognisance. A debt on recognisance takes precedence of other debts, and binds the lands of the cognisor from the time of its enrolment. If the recognisance is made to a private individual in the nature of a statute staple, &c., he may on its forfeiture, by virtue of process directed to the sheriff, obtain delivery of the lands and goods of the cognisor till the debt is satisfied, or proceed against the cognisor in an action of debt, or by scire facias. If the recognisance is made to the crown, it was formerly, in all cases of forfeiture, estreated into the exchequer, and afterwards recovered by process from that court to the use of the treasury. But now forfeited recognisances taken before the court of quarter-sessions, or justices of the peace, are enrolled among the sessions records, and recovered by the sheriff; a list of the amounts being yearly returned by the clerks of the peace and town-clerks for their districts respectively, to the lords of the treasury. Where a recognisance has been estreated into the exchequer, that court may discharge or compound it according to the justice of the case.

RECONNOISSANCE is an examination of a tract of country or of the sea-coast; the latter previously to a disembarkation of troops, and the former preparatory to the march of an army in order either to meet that of the enemy or to take up quarters for the season.

The *military reconnoissance* of a country is a duty appertaining primarily to the officers on the staff of the quartermaster-general, though in many cases, such as sieges, &c., it is necessarily carried out by the engineers; and if the enemy is in the neighbourhood, it is performed under the protection of an armed force. It is considered as one of the most essential operations connected with the tactics of the field, and serves as the basis of every movement or combination which it may be proposed to make.

A general knowledge of a country which is or may become the seat of war—that is to say, a knowledge of the positions of its fortified places, the directions of its mountains, rivers, and great roads—may be obtained from maps or from geographical descriptions; but that which is necessary for the immediate purposes of a campaign can only be acquired by an actual survey of the ground in detail, and by inquiries made on the spot respecting the means which the country may afford for supplying the wants of the army.

The Maréchal Puysegur (1690) appears to have been the first in modern warfare who regularly performed this duty by examining personally the tract through which the army was to march, or in which it was to encamp, and of deciding beforehand on the best routes and positions. He observes ('Art de la Guerre') that before his time it had been customary to trust for a knowledge of these points to the reports of the country-people, or of officers who might accidentally have been on the ground. He adds that disasters frequently occurred by the lines of march being improperly chosen, and that sometimes, after fatiguing marches, and after all the labour of encamping had been undergone, the troops had been compelled to abandon the positions on account of their unfitness. Since that time, armies being more numerous and more widely disseminated, consequently requiring more vigilance in the communication of one part with another, and a greater extent of country for their support, the reconnoissances have been made on a greater scale, and in the military establishments of every nation officers are now particularly instructed in all the details of that branch of service.

Those who are charged with this duty should be habituated to the performance of topographical surveys: in the first place by the most accurate methods and with the best instruments; and secondly, by such methods as admit of being practised rapidly on foot or on horseback. In these cases, an azimuth compass held in the hand must be used for observing the angles, and the distances must be obtained by pacing, or be merely estimated by the eye. A micrometer scale, divided to 200ths of an inch, fixed in the eye-piece of a telescope, will give distances with comparatively great accuracy and great ease, as it is only necessary to see how many divisions an object subtends, and on arriving at it to measure it, the focal length of telescope having been previously determined by experiment. A facility in representing on the plan the inequalities of the ground is also highly necessary.

In making the reconnoissances previously to the march of an army, the whole of the ground between the actual position of the latter and that which is intended to be occupied should be surveyed if the enemy is near and there is danger of his attacking the columns by surprise; otherwise it may be sufficient to survey the ground within a few hundred paces on each side of the roads by which the columns are to march. A complete plan of the tract of country in which the reconnoissance is made may therefore be required; or it may suffice to represent on paper the line or lines of march. In either case the officer may be provided with a general map, or an itinerary of the intended route, as an outline for his guidance; and his survey, when completed, should be accompanied by a report or memoir, stating in detail what cannot be conveniently represented on the plan. In this report should be expressed, with all necessary references to the plan of the ground, the distances, by the different routes, between the two positions, and the places where troops may halt for repose or to form in order of battle, distinguishing particularly the plains where cavalry may act, and the heights on which artillery may be placed. The nature of the roads should be described, with indications denoting that they are passable for artillery, for cavalry, or merely for infantry; and if defective, estimates should be made of the materials and time requisite for repairing them. It is particularly necessary to state whether the ascents and descents are gentle or abrupt; and, when the road is on the side of a hill, whether it is sufficiently level to allow artillery or carriages to pass safely. It should also be noticed whether or not, at places where roads run through towns, they are reduced to narrow and winding streets. The breadths and velocities of rivers, streams, and canals which cross the lines of march should be ascertained, and a statement made whether the beds are rocky, gravelly, or muddy; also whether the banks are high or low. Mention should also be made of the means which exist for passing them; of the places where they are fordable, where there are ferries or bridges, or where boats may be procured: descriptions should also be given of the bridges or boats, and the manner of working the latter. The situations and extent of marshes should also be shown, and it should be stated whether they are passable or can be made so. In contemplating rivers and marshes as means of retarding an advance of the enemy, it should be ascertained and reported whether, by being dry in summer or frozen in winter, they may not at times cease to be obstacles. It should also be stated how, on a retreat, the roads may be blocked up, the fords rendered impassable, or the bridges destroyed.

Should a sufficient number of roads for the different columns not exist, the officer is to ascertain whether or not others may be made by cutting through hedges, walls, or woods, by forming causeways over marshes, or by constructing or repairing bridges over rivers or streams; and also whether the country affords the materials necessary for these purposes. The rates at which it is possible for troops to march in the several roads, defiles, &c., must be estimated according to the breadth of the latter or the degree of their practicability; for on a right estimate of such rate, together with the known length of the road, depend the number of battalions and the class of troops which ought to be appointed to follow each particular route, when it is required that the different columns should arrive at the same time in some given position. The plan should show the situations of farms, mills, houses, &c., which may be capable of being defended or of affording quarters for the troops; and on it should be indicated, by some scale of numbers or otherwise, the relative heights of the ground, that it may be ascertained what positions can be occupied with advantage for offensive or defensive operations. The representation of a simple line of march should also indicate the places where roads diverge from or cross the route, with the distances of the nearest towns or villages from thence; and any particular survey of the ground for an encampment should extend to at least a mile every way beyond the supposed chain of outposts. [Military Positions; Piquet.] The report must state what are the resources of the country in corn, cattle, and forage; and the number of carriages, horses, and other draught animals that it may furnish for the conveyance of artillery and stores. If the line of march is in the direction of a navigable river which may be available for the last-mentioned purpose, it will be necessary to ascertain its breadth and rapidity, and also the obstructions which may be met with from shallows, weirs, &c. Marshal Suchet caused his artillery to be conveyed by the Ebro from Mequinenza to Xerta, in 1810, preparatory to forming the siege of Tortosa.

An open country presents the greatest facilities for reconnoitring, since the positions of its towns or villages, and the directions of its roads and rivers, can then be easily distinguished and represented on paper. A tract covered with wood is not only surveyed with difficulty, but it imposes on the officer, in addition, the necessity of ascertaining all the directions in which it is capable of being penetrated by the enemy, and in what manner the passes may be blocked up or defended. Open plains intermingled with wood, fields surrounded by hedges, ground intersected by streams of water, ravines, and hollow ways, demand great exactness in the survey, since such tracts afford the most important advantages, both in the higher and in the secondary operations of warfare, to the army which is best acquainted with their details. They allow troops to pass unseen from one point to another when a surprise is attempted or a rapid retreat is to be made; they also afford cover from whence the enemy may be annoyed with little loss. In mountainous districts it is important to ascertain the forms and directions of the chains of heights, with their acclivities on both sides; and, if the line of march is between them, the collateral ravines should be examined to a considerable distance: the commencements and directions of the ravines should also be shown, and all the defiles by which the valleys communicate with each other. Through these defiles troops detached from the army are enabled to fall suddenly on the enemy during his march, to separate his columns, and intercept his supplies or cut off his retreat; and, on the other hand, since the enemy may attempt the like measures, it becomes necessary that the officer employed to reconnoitre should ascertain by what means the passes may be barricaded, either to impede the enemy or enable the troops to defend themselves.

In reconnoitring a country, when it is intended to act on the defensive, it should be well known by what roads the enemy can penetrate, and where are the best situations for forming intrenched camps or establishing posts in order to be enabled to keep the field and cover the magazines. Again, if it be intended to carry the war into an enemy's country, it is necessary to discover the position occupied by his army; to find the tract of country most proper for the march, and the spots where the localities permit encampments to be formed with due support on the flanks and security in the rear. If it be intended to besiege a fortress or to attack the enemy's position, the reconnoissance may be made quite up to the glacis of the place, or to the works which protect the position. In the former case it is necessary to ascertain the nature of the fortifications, and the fitness of the ground about them for the operations of the siege; and in the latter, to find out the strength and dispositions of the enemy's troops. An armed force is generally required on these occasions, as, in order to approach near enough for the purpose, it may be necessary to drive in some of the outposts. During the war which ended in 1814, the English and French out-sentries appear to have entertained a mutual understanding not to molest each other, and to retire to their supports before they commenced firing when either army was about to make a movement. Colonel Napier relates that Lord Wellington, being once desirous of reconnoitring the enemy's position at Bayonne, ordered his escort to fire upon some of the enemy who occupied the top of a hill which he wished to ascend; but one of the men going up to the French soldiers and tapping his musket in a particular way, the latter, who understood the signal, quietly withdrew.

In a *maritime reconnoissance* the circumstances which it is of most importance to ascertain are: whether the coast is rocky or bordered by downs, and what is the state of the bays or roads with respect to shelter from the prevailing winds; the seasons in which winds blow off and on the shore, and whether the anchorage is secure or otherwise; the nature of the tides, the hours of high and low water, and the depth at either of those times. Precise information should also be obtained of the places at which troops might land, and where there exist rising grounds on which artillery may be disposed to protect them. Rivers should be ascended to a considerable distance if possible, in order to ascertain their depths and the nature of the vessels employed on them by the people of the country. On the other hand, if it were required to examine the coast preparatory to putting it in a state of defence, it would be necessary to find out what points of land are convenient for the situations of forts or batteries by which the enemy may be prevented from landing, and where beacons may be established for the purpose of giving timely alarm. If there are islands on the coast, it would be proper to include them in the survey, since they might be fortified and made to serve as advanced works; and all places should be indicated which are capable of being converted into military posts to prevent the enemy from penetrating into the interior of the country.

RECORD, a memorial in rolls of parchment of the proceedings and acts of a court of law, upon whose proceedings error will lie. An act of a party which is put on record cannot be varied even in the same term, but a judicial act of the court may be altered during the same term. If a record is lost, the court may order a new entry to be made at any time. In order to prove a record the existence of which has not been denied on the pleadings, an examined copy is sufficient. But if the existence is denied on the pleadings, it can only be proved upon inspection by the court of the record itself; and that is conclusive not only as to the existence of the record, but as to all matters stated in it. For the record of a court of competent jurisdiction is legally considered as the indisputable proof of all those proceedings having taken place which the record sets forth; and no averment to the contrary in pleading can be made. A record found in the proper office is legally assumed to have been always in the same plight in which it is found. The effect of a reversal of a judgment in error is to annul the previous record from the commencement. ('Co. Litt.,' 117 b., 260 a.; Com. 'Dig.,' tit. 'Record.') As to what constitutes a Court of Record, see Courts, and Recorder.

RECORDER (*Recordator*), a judicial officer, described by Cowell as "he whom the mayor or other magistrate of any city or town corporate having jurisdiction, or a court of record, within their precincts by the king's grant, doth associate unto him for his better direction in matters of justice and proceedings according to law." The Norman term, *recordeur*, appears to have originally been applied to every person who was present at a judicial proceeding, and to whose remembrance, or record, of what had taken place the law gave credit in respect of his personal or official weight and dignity. Of this we perceive a trace in the ordinary writ of Accedas ad Curiam, by which the sheriff is commanded to go to some inferior court (which, not being the king's court, is not a court of record), taking with him four knights, and there to record the plaint, which is in that court; the remembrance of the four knightly recordeurs of what they saw existing in the inferior court, in obedience to the king's writ, being treated as equivalent to their actual presence at the proceeding to be recorded. So if the proceedings are in the sheriff's court, he is ordered by the writ of Recordari facias loquelam to cause the plaint to be recorded by four knights. And by a record of the 8th year of King John, we find that a judgment of battle in the court of the archbishop of Canterbury being vouched in the king's courts, four knights were sent to inspect the proceedings, who returned "quod recordati sunt.' ('Placitorum Abbreviatio,' 54.) The practice of certifying and *recording* the customs of London *by the mouth of the recorder*, which is antecedent to the charters granting or recognising the practice, appears to be referrible to the same source. Where criminal or civil jurisdiction was exercised by citizens or burgesses, it would add to the importance of the court if its proceedings took place in the presence of an officer to whose *record* the superior courts would give credit, either in respect of his personal rank, as a peer or knight, or on account of his connection with those courts, as a serjeant or barrister-at-law. [SERJEANT.]

Since 1835 the duties of recorders in the cities and boroughs coming within the operation of the Municipal Corporations Act (5 & 6 Will. IV., c. 70), have been regulated by the provisions of that and of subsequent statutes. The jurisdiction of the recorder in places of minor importance will not require to be noticed. Nor do these acts affect the city of London.

I. The recorder of London is a judge having criminal and civil jurisdiction. He is also the adviser and the advocate of the corporation. In respect of the duties performed by the recorder in the assemblies of the corporation, in the courts of mayor and aldermen, of common council, and of common hall, his office may be said to be ministerial. He is by charter a justice of the peace within the city of London, and a justice of oyer and terminer, and a justice of the peace, in the borough of Southwark.

The first charter of Edward IV. to the city of London grants that the customs of the city be certified and *recorded* by word of mouth, and that the mayor and aldermen of the city and their successors do declare by the recorder whether the thing under dispute be a custom or not.

The business of the mayor's court, in which the recorder ordinarily presides alone, comprehends a court of equity. In the mayor's court the recorder tries civil causes, both according to the ordinary course of common law and the peculiar customs of the city. The amount for which such actions may be brought is unlimited.

All the duties of a justice of the peace, including those of chairman, devolve upon the recorder at the quarter and other sessions held at Guildhall for the city of London. At the twelve sessions which are held yearly at the Old Bailey, the recorder acts as one of the judges under her majesty's commission of oyer and terminer, and general jail delivery.

The annual salary of the recorder of London is 3000*l.* Besides this, he has fees on all cases and briefs which come to him from the corporation, and he is also allowed to continue his private practice.

The recorder is elected by the court of aldermen, most commonly at a special court held for the purpose. Any alderman may put any freeman of the city in nomination as a candidate for the office, but an actual contest seldom takes place. The recorder elect is admitted and sworn in before the court of aldermen. The appointment is during good behaviour, that is, in contemplation of law, for life. The recorder has always been a serjeant-at-law or a barrister. The office has been held by men of considerable eminence: of eleven persons who filled the situation during the last century, one became lord chancellor; another, master of the rolls; another, chief justice of the Common Pleas; and two, barons of the Exchequer.

By an order made by the court of aldermen in the reign of Philip and Mary, the recorder, common-serjeant, and judge of the sheriff's court, were directed to be chosen "from old and learned officers of the city or out of the number of the six learned counsellors," that number comprehending, in addition to the ordinary city counsel, the attorney and solicitor-general, who were always retained for the city. Four persons by whom the recordership of London has been held during the present century, have previously filled the office of common-serjeant. [SERJEANT.] But no similar instance occurred during the 18th century.

The recorder of London deriving his authority from charters, and not being appointed by commission (except temporarily as included with other judges in the commission of oyer and terminer, &c., at the Old Bailey), he is not, like the judges of the superior courts, liable to dismissal by the crown upon an address by both Houses of Parliament. But all recorders may be removed for incapacity or misconduct by a proceeding at common law.

Deputy recorders have, in some instances, been appointed by the court of aldermen on the nomination of the recorder. ('Report on Municipal Corporations.')

II. In cities and boroughs within the Municipal Corporations Act, the recorder (who must be a barrister of not less than five years' standing) is a judicial officer appointed under the sign manual by the crown during good behaviour, having criminal and civil jurisdiction within the city or borough, with precedence next to the mayor. He holds once in every quarter of a year, or at such other and more frequent times as he shall in his discretion think fit, or as the crown shall think fit to direct, a court of quarter-session of the peace, at which he sits as the sole judge, such court being a court of record, and having cognisance of all crimes, offences, and matters whatever cognisable by any court of quarter-session of the peace for counties in England. No recorder has power to make or levy any rate in the nature of a county-rate, or to grant licence to keep an alehouse or victualling-house, to sell exciseable liquors, or to exercise any of the powers by that act specially vested in the town council.

The civil jurisdiction of the recorders of boroughs is exercised in the borough court, according to the charters or acts of parliament, if any, which regulate them. He may, however, delegate this duty to a judge of the court.

RECORDER, a musical instrument formerly in use; "a flageolet or small English flute, the mouthpiece of which, at the upper extremity of the instrument, resembled the beak of a bird; hence the larger flutes so formed were called *flutes à bec.* The recorder was soft in tone, and an octave higher than the flute. Milton speaks ('Par. Lost,' i. 550) of

> "The Dorian mood
> Of flutes and *soft recorders.*"

It would appear, from Bacon's 'Sylva Sylvarum,' cent. iii., 221, that this instrument was larger in the lower than in the upper part; and a wood-cut of the flageolet in Mersenne's 'Harmonie Universelle,' leads to the same conclusion. On the etymology of the word much ingenuity has been bestowed, but without any satisfactory result." (Note in 'Pict. Shaksp.,' Hamlet, Act iii., Sc. 2.)

RECORDS, PUBLIC. Authentic memorials of all kinds, as well public as private, may be considered in one sense as records. Thus the Metopes of the Parthenon are indisputable records of Grecian art; the journal stamp on a letter is a record that it has passed through the post-office; a merchant's letter is a record of his business; and every lord of a manor may keep written records of his courts, as the chancery, the exchequer, and other courts do of their proceedings. But our present purpose is to give some general account of the public records, properly so called, understanding by the term the contents of our Public Record Office.

Records, in the legal sense of the term, are contemporaneous satements of the proceedings in those higher courts of law which are distinguished as courts of record, written upon rolls of parchment. (Britton, c. 27.) Matters enrolled amongst the proceedings of a court, but not connected with those proceedings, as deeds enrolled, &c., are not records, though they are sometimes in a loose sense said to be "things recorded." In a popular sense the term is applied to all public documents preserved in a recognised repository; and as such documents cannot conveniently be removed, or may be wanted in several places at the same time, the courts of law receive in evidence examined copies of the contents of public documents so preserved, as well as of real records. [COURTS; RECORD; RECORDER.]

The course we propose to take, is to treat that as a record which is thus received in the courts of justice. The act, for instance, which abolished Henry VIII.'s court of augmentation (of the revenues obtained from the suppression of the religious houses), declared that its records, rolls, books, papers, and documents, should thenceforth be held to be records of the court of exchequer; and accordingly we have seen many a document, originally a mere private memorandum, elevated to the dignity of a public record, on the sole ground of its official custody, and received in evidence as a record of the Augmentation-office. On the other hand, numbers of documents which were originally compiled as public records, having strayed from their legal repository to the British Museum, have thereby lost their character of authenticity. ('Proceedings of the Privy Council,' vol. v., p. 4, edited by Sir Harris Nicolas.)

"Our stores of public records," says Bishop Nicolson, and, we believe, with perfect accuracy, "are justly reckoned to excel in age, beauty, correctness, and authority, whatever the choicest archives abroad can boast of the like sort." (Preface to the 'English Historical Library.')

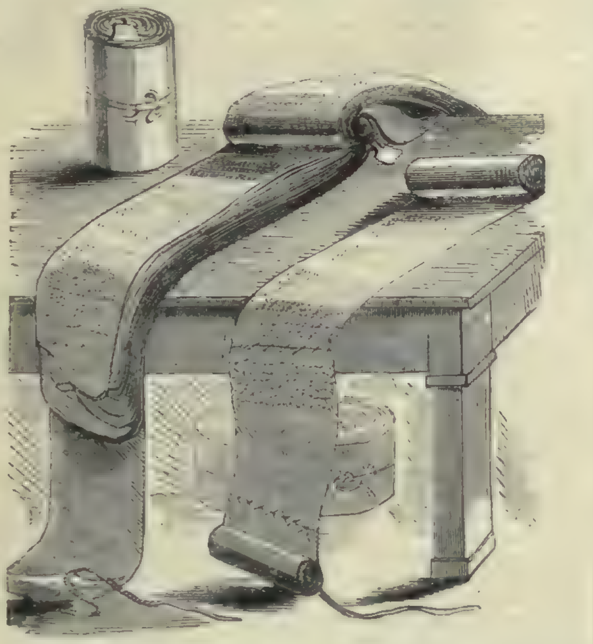
By far the greater part of records are kept as rolls written on skins of parchment and vellum, averaging from nine to fourteen inches wide,* and about three feet in length. Two modes of fastening the skins or membranes were employed,—one, that of attaching all the tops of the membranes together bookwise, which is employed in the exchequer and courts of common law; the other, that of sewing each membrane consecutively, which was adopted in the chancery and wardrobe.

The solution of the reasons for employing two different modes has been thought difficult by writers on the subject. It appears to have been simply a matter of convenience in both cases. The difference in the circumstances under which these rolls were formed, accounts for the variation of make. In the first case, each inrolment was often begun at one time and completed at another. Space for the completion of the entry must have been left at hazard. Besides, several scribes were certainly engaged in inrolling the proceedings of the courts, and the roll was liable to be unbound, and to receive additional membranes after it had once been made up. In the other case, the business of the chancery being simply registration, the scribe could register the documents before him, with certainty that nothing in future would affect their length, and he was enabled to fill every membrane, and perfect the roll as he proceeded.

---

* The rolls of the Great Wardrobe exceed eighteen inches in width.

In the *volumina*, or *scapi*, of the ancients, the writing was carried in equal columns, as in the pages of a book, along the length of the skin, but the inrolment in both sorts of our rolls is written across the width of the membrane. The rolls of the common law, after the time of Henry VIII., contain so many skins that they cease to be rolls, but become simply oblong books, and, unlike the early rolls of the same series, are exceedingly ill-adapted for preservation and inconvenient for use. There are many of these miscalled rolls of the reign of Charles II., which in shape, size, and weight resemble the largest Cheshire cheese, often requiring two men to lift them from the rack. Membranes may be fastened together after the chancery fashion in any numbers, and yet remain a legitimate roll, though imposing much bodily labour in the consultation. The land-tax commissioners' Act of 1 Geo. IV. extends, it is said, 900 feet when unrolled. Other records have the shape of books. Doomsday Book, called both 'Rotulus' and 'Liber,' the oldest and most precious of our records, counting eight centuries as its age, and still in the finest order, is a book; and as occasions presented themselves for adopting this shape without infringing on ancient precedent, the far more accessible shape which we now call a "book" seems to have been employed. A considerable part of the records of the courts of the surveyor-general and augmentations, in the reign of Henry VIII., of wards and liveries, and requests, are made up as books. Other documents, those relating to fines, the 'Pedes Finium or Finales Concordiæ,' the writs of 'Dedimus Potestatem,' and acknowledgments and certificates, writs of the several courts and returns, writs of summons and returns to parliament, inquisitiones post mortem, &c., &c., by tens and hundreds of thousands are filed, that is, each document is pierced through with a string or gut, and thus fastened together in a bundle.



The material on which the record is written is generally parchment, which, until the reign of Elizabeth, is extremely clear and well prepared. From that period until the present, the parchment gradually deteriorates, and the worst specimens are furnished in the reigns of George IV. and William IV. The earliest record written on paper, known to the writer, is of the time of Edward II. It is one of a series entitled, 'Papirus magistri Johannis Guicardi contra-rotulatoris Magnæ Costumæ in Castro Burdegaliæ, anno domini M°. ccc°. viii°.' These records are in the office of the queen's remembrancer of the exchequer.

Tallies were records of wood. [TALLY.]

The handwriting of the courts, commonly called court-hand, which had reached its perfection about the reign of our second Edward, differs materially from that employed in chartularies and monastic writings. As printing extended, it relaxed into all the opposites of uniformity, clearness, legibility, and beauty which it once possessed. The ink too lost its ancient indelibility; and, like the parchment, both handwriting and ink are the lowest in character in the later times; with equal care, venerable Domesday will outlive its degenerate descendants.

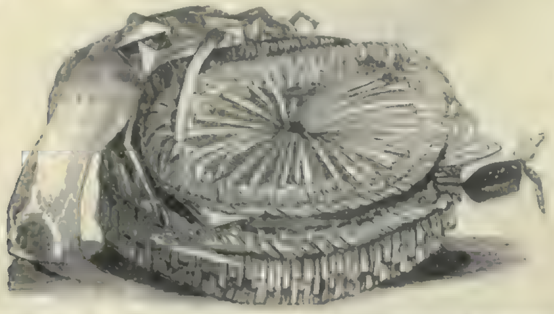
All the great series of our records, except those of parliament, are written in Latin, the spelling of which is much abbreviated. The reader who desires to be further informed on the subject may consult the collections of contractions which Mr. Hardy has inserted in the preface to his 'Close Rolls of King John,' and Mr. Hunter, in his preface to the 'Fines of Richard I. and John.' During the Commonwealth, English was substituted; but soon after the Restoration, Latin was restored, and the records of the courts continued to be kept in Latin until the reign of George II. In certain branches of the exchequer, Latin continued in use until the abolition of the offices in very recent times. Many of our statutes from Edward I. to Henry V., and the principal part of the rolls of parliament, are written in Norman French. Petitions to parliament continued to be presented in Norman French until the reign of Richard II., whose renunciation of the crown is said to have been read before the estates of the realm at Westminster first in Latin and then in English. After this period we find English often used in transactions between the people and government, a sure sign that the distinctions of Norman origin were nearly absorbed among the people at large.

Sir Francis Palgrave's edition of the 'Calendars and Inventories of the Treasury of the Exchequer,' some of which were compiled as early as the 14th century, are extremely interesting in exhibiting the ancient modes in which records were preserved. No uniform system of arrangement seems to have been employed, but a different expedient was used for the preservation of nearly every separate document. Great numbers, judging from the quantity found in arranging the miscellaneous records of the queen's remembrancer of the exchequer, were kept in pouches or bags of leather, canvas, cordovan, and buck ram, a mode which is still used in this department of the exchequer. These pouches, which fasten like modern reticules, are described by Agarde, who was keeper of the Treasury of the Exchequer, "as hanging against the walls." The following drawing represents a leathern pouch containing the tallies and the account of the bailiff of the manor of Gravesend in the 37 and 38 of Edward III.

When they have escaped damp, they have preserved their parchment contents for centuries in all their pristine freshness and cleanliness. Chests, coffers, coffins, and "forcers" bound with iron and painted of different colours, cases or "scrinia,"* "skippets," or small turned boxes, and hanapers, or "hampers of twyggys," were also used.

---

* The Romans kept their records in 'Scrinia,' respectively distinguished as 'Scrinia Viatoria; Scrinia Stataria; Scrinia Palatii; Scrinia Sacra; Scrinia Augusta.'



Inscriptions on labels, letters, and "signs" furnished the means of reference. We owe the following specimens of these "signs" to the kindness of Sir Francis Palgrave, who has obliged us with the lean of the blocks, cut for his calendars of the exchequer before mentioned. These signs in most cases bear analogy to the subject of the documents which they are intended to mark.

The rolls of the justices of the forest were marked by the sapling oak (No. 1). Papal bulls by the triple crown (2). Four canvas pouches holding rolls and tallies of certain payments made for the church of Westminster were marked by the church (3). The head in a cowl (4) marked an indenture respecting the jewels found in the house of the Fratres Minores in Salop. The scales (5), the assay of the mint in Dublin. The Briton having one foot shod and the other bare, with the lance and sword (6), marked the wooden "coffin" holding the acquittance of receipts from Llewellin, Prince of Wales. Three herrings (7), the "forcer" of leather bound with iron, containing documents relating to Yarmouth, &c. The lancer (8), documents relating to Aragon. The united hands (9), the marriage between Henry, Prince of Wales, and Philippa, daughter of Henry IV. The galley (10), the recognisance of merchants of the three galleys of Venice. The hand and book (11), fealty to kings John and Henry. The charter or cyrograph (12), treaties and truces between England and Scotland. The hooded monk (13), advowsons of Irish churches. And the castle with a banner of the Clare arms (14), records relating to the possessions of the earl of Gloucester in Wales.

Our ancestors before the Norman conquest pursued no system of public registration. There are numerous charters of the Anglo-Saxon kings and deeds between private individuals still existing: six volumes of these were edited by the late most able scholar, John Mitchell Kemble, under the title of 'Codex Diplomaticus ævi Saxonici, but even he did not exhaust the precious store. Historical events were chronicled in monastic chartularies.

The Anglo-Saxons, whose judicial proceedings were conducted orally, had no records except the "land-boes" or charters. The transactions of the folk-moots were not registered or *recorded*, and in the administration of justice no reference was made to written precedents. In such a state of society, though the actual possession of land constituted one of the best titles to real property, still the "land-boc" furnished evidence of it also. And so important were these land-books considered, that when the monks of Ely purchased seven hydes and a half of land, they gave three hydes, besides thirty "aurei," to recover the charter or "cyrograph" of the title. Duplicates and triplicates of these land-books were made, and one "part" was delivered into the custody of the Burthegn, or chamberlain, to be preserved in the "horde," or royal treasury.

When a written account is made of any act, it is clear that it is made not for the exclusive benefit of one party only. In the Domesday Book of the Norman conqueror, we see evidence that his power was far from absolute. The financial registrations (Rotuli Pipæ) of Henry I., in whose reign the earliest example is found—the records of the judicial proceedings of the "Curia Regis," which begin with Richard I.—and the special acts of the monarch himself enrolled on the "close," "patent," and "charter" rolls commencing in the reign of John—are all so many irresistible proofs how larger interests were gradually trenching on the will of the king. The judicial records of the King's Bench and Common Pleas, and the parliamentary records beginning with Edward I., are further evidence of the increasing influence of the nobles and commonalty of the realm.

The king was legally considered as possessing the sovereign power. His peace was broken when the subject fell by the hand of the murderer; his parliament was to be summoned; his honour to be vindicated; and his army to be levied. It was the king's exchequer, the king's wardrobe, the king's court, and essentially the king's chancery; for the chancellor's functions were originally those of a private secretary, combining duties both spiritual and temporal. Holding the keepership of the king's conscience, the chancellor was necessarily of the clerical body, and the chief of the king's chapel. The great seal was in his custody, and the scope of his secretarial duties embraced all those of modern times performed by our secretaries of state for the home and foreign departments; and of all the business transacted a systematic and orderly registration was preserved in the several inrolments called "patent," "close," "charter," &c. All records of these several departments formed part of the king's treasure; and, in accordance with the practice of the ancient Persians five hundred years before the Christian era, when Darius caused a search for the decree of Cyrus to be "made in the house of the rolls, where the treasures were laid up in Babylon" (Ezra, vi. 1), were deposited in the king's "treasuries."* The mutual interest of all parties naturally made the preservation of the records an object of general solicitude; to the king, as they furnished indisputable precedents for his calls of military service and taxation; to the nobles, in protecting them in their feudal rights and various privileges; and to the commons most of all, in limiting the powers both of king and nobles, sheltering them from capricious extortion, and securing to them a certain amount of consistency in the administration of justice.

In Henry III.'s reign there were royal treasuries of records in the Tower of London and the New Temple. From the latter place, in the 20th of Edward I., out of a chest secured by nine keys, certain records of the Chancery were taken by the king's orders. ('Rot. Claus.,' 20 Edward I., m. 13 d.) The Tower had certainly become a permanent treasury for records in the 33rd of Edward I., when a transfer to it was directed to be made of all the papal privileges touching the crown or kingdom, from the treasury of the exchequer at Westminster. ('Rot. Claus.,' 33 Edward I., m. 3.) Another "treasury" is described by certain "memoranda," made 19 Edward III., as within the cloister of Westminster Abbey, near the Chapter-House (thesauraria Regis infra Claustrum Abbatiæ Westmonasterii juxta Capitulum). This "treasury" still remains. A single pillar supports the vaulted chamber, which is yet to be seen, with its double oak doors grated and barred with iron and locked with three keys, and its drawers and "tills" labelled by Arthur Agarde, who was custos of the records it contained. In his 'Compendium of the Records in the Treasury,' compiled 1610, he says that "the recordes of the kinge's majesties threasury at Westminster, under the custodie of the lord-threasurer and the two chamberlaines, were lay'd up for their better preservacion in fower severall threasauries under three severall kayes, kept by three sondry officers, distinct the one kay from another, and uppon each dore three lockes. The first in the Court of Receipt; the seacond in the Newe Pallace at Westminster, over the Little Gatehouse there; the third in the late dissolved abbey of Westminster, in the Old Chapter-House; the fourth in the cloister of the sayd abbey."

The contents of several "treasuries" at various periods seem to have been consolidated in the Chapter-House of Westminster Abbey, which was fitted up for the reception of records by Sir Christopher Wren.

---

* Certain records of the Chancery followed the king in his migrations over the kingdom as late as Richard II. Religious houses were called upon to provide horses for the conveyance of them. Edward I., by writ, tested the 4th July, in the twenty-eighth year of his reign, commanded the abbot of Furness to provide a strong horse to carry the Chancery Rolls to York.

The demolition of the old "treasuries" adjoining Westminster Hall scattered their contents in all quarters of the metropolis. Thus the records of the king's remembrancer, of the Exchequer, and the Common Pleas, migrated from Westminster Hall to the late Mews at Charing Cross; and thence, to make room for the National Gallery, to Carlton Riding-School. The records of the late lord-treasurer's remembrancer and Pipe-Office were entombed two stories deep in the vaults of Somerset House. Those of the King's Bench for a time rested opposite St. Margaret's Church, but were shifted to the Roll's-House in Chancery Lane to make room for the present Rolls Court at Westminster.

Thus from time to time had repositories, as well undignified with the ancient title of "king's treasury" as deficient in that careful superintendence which originally accompanied the title, arisen in all parts of London; and in 1837 a Committee of the House of Commons reported that it had seen the Public Records, the most precious part of the king's "treasure," deposited at the Tower over a gunpowder-magazine, and contiguous to a steam-engine in daily operation; at the Rolls, in a chapel where divine service is performed; in vaults two stories underground at Somerset House; in dark and humid cellars at Westminster Hall; in the stables of the late Carlton Ride; in the Chapter-House of Westminster Abbey.

It would seem that as early as the commencement of the 14th century the officers charged with the custody of the records were found to be either insufficient or neglectful of the performance of their duties. Since the time of Edward II. scarcely a reign has passed without a special temporary agency being appointed to restore the public records to good order. The necessity probably arose from the functions of the officer charged with the care of the records being altogether changed, as in the instance of the master of the Rolls, who was the *bonâ fide* "gardein des roules" in early times.

In the 14th Ed. II., the barons of the Exchequer were directed to employ competent clerks to methodise the records, which were "not then so properly arranged for the king's and the public's weal as they ought to be." Again in the 19th year of Ed. II., certain commissioners were appointed for a similar purpose. In Edward III.'s reign, at least three like commissions were issued ('Rot. Claus.,' Annis 34 and 36; and 'Rot. Parl.,' Anno 46). Statutes for the protection of records from falsification, erasure, and embezzlement were passed 8 Rich. II. c. 4, and 11 Hen. IV. c. 3. Other measures were taken by Hen. VI., Hen. VII., and Hen. VIII. Inquiries into the state of the Parliamentary, the Chancery, and Exchequer Records were prosecuted by Queen Elizabeth, who also established the State Paper Office, in which the proceedings of the secretaries of state from her days to the present are preserved. Committees of both Houses of Parliament from time to time visited the several repositories, and the fire of the Cottonian Library in 1731 produced a report which describes the condition of most of the public repositories at that period. But the fullest examination into the state of the public records which has been made in recent times was effected by a Committee of the House of Commons, in 1800, conducted by Lord Colchester, then Mr. Abbot, and the report of that Committee presents by far the most perfect and comprehensive account which has yet appeared of our public records, to which a period of sixty years has added very little. This Report originated a commission for carrying on the work which its authors had begun. The Record Commission was renewed six several times between the years 1800 and 1831, and was altogether suspended at the accession of Her Majesty Queen Victoria. All the several record commissions recited, one after another, that "the public records of the kingdom were in many offices unarranged, undescribed, and unascertained;" that they were exposed "to erasure, alteration, and embezzlement," and "were lodged in buildings incommodious and insecure." The commissioners were directed to cause the records to be "methodised, regulated, and digested," bound and secured; to cause "calendars and indexes" to be made and "original papers" to be printed; but the record commissioners expended the funds entrusted to them rather in printing records than in arranging or calendaring them. A very full investigation into the proceedings of the record commission was made by a Committee of the House of Commons in 1835, and the reader who is curious to know more than our space allows us to state, may consult its Report, and the series of Reports since made by the Deputy Keeper of Public Records, which are published annually. Certainly during the present century there has been no niggard expenditure in one shape or another in respect of the public records. It is not very easy to ascertain its total amount, but the following may be received as an approximation up to the year 1839:—

Parliamentary Papers show that grants were made on behalf of the Record Commission between 1800 and 1831, to the amount of	£362,400
Between 1831 and 1839 inclusive	125,700
Salaries, &c., for the custody of Records	120,000
Fees, estimated on an average of the years 1829, 1830, and 1831, at least	120,000
Removals of Records, estimated at	30,000
	758,100
Irish Record Commission, estimated at	120,000
	£878,100

A very important step was taken by the legislature at the commencement of her Majesty's reign to provide for the better custody and preservation and more convenient use of the public records, and an act was passed (1 & 2 Vict., c. 49) calculated to remedy effectually what preceding efforts had in vain attempted, by constituting a special agency for the custody of the records; to the want of which and a sufficient responsibility, all the defects of the old system are attributable. By this act the Master of the Rolls is made the guardian of the public records, having powers to appoint a deputy, and, in conjunction with the treasury, to do all that may be necessary in the execution of this service. The act contemplates the consolidation of all the records, from their several unfit repositories, into one appropriate receptacle; their proper arrangement and repair; the preparation of calendars and indexes, which are more or less wanting to every class of records; and giving to the public more easy access to them. Lord Langdale, the late master of the rolls, to whose influence the change of system is greatly due, brought the above act into as full operation as circumstances allowed while he lived; and his successor, the Right Hon. Sir John Romilly, has, with untiring patience, watched and fostered the collection of the Public Records into the costly building now erected near Fetter Lane, where almost any document of public interest may be consulted gratis by the literary inquirer, and by the legal profession for legal purposes under the following regulations and fees.

Extract from the Regulations made by the Right Honourable the Master of the Rolls, concerning the gratuitous admission of literary inquirers to the Public Records, including the State Papers.—July 5, 1858.

That the individuals seeking to avail themselves of the permission, shall address a letter to the deputy keeper, stating generally their objects of research, and that the applicant shall also, if needful, attend the deputy keeper personally thereon, and give such further explanation as may be required; and that thereupon the deputy keeper shall, if satisfied with the statement and explanation, issue a permission empowering the applicant or any trustworthy agent or transcriber on his behalf, to inspect all indexes of records, and original records, and also to make copies or extracts, without payment of fees. It will be necessary also to explain to applicants that the literary inquirer will have free access to the documents; but this being done, he will have to conduct the inquiry in such manner as his own knowledge and experience may best enable him to do.

Fees.

	£	s.	d.
I. For searching calendars, indexes, or other books of reference, each day	0	1	0
II. For inspection of any document, each day	0	1	0
„ of any number of documents above five, each day	0	5	0
Any roll, book, portfolio, file, or bundle, to be considered as one inspection.			
The inspection fee will be remitted when a copy is ordered *at the time of inspection.*			
III. For copies, at 72 words each folio:—			
Under three folios	0	2	0
Three folios and upwards, each folio	0	0	9
All copies are to be authenticated.			
IV. For attendance at either house of parliament, to be sworn	1	1	0
For attendance at either house of parliament, or elsewhere, to give evidence; or with ten records or less number: each day	2	2	0
Ditto, ditto, for each additional record, each day	0	2	0
For attendance on the Master of the Rolls on a vacatur	1	1	0

We can only find space to glance at the particular classes of the public records, noticing in the fewest words the more ancient and valuable. No enumeration we could give would enable the reader to dispense with reference to the inventories, repositories, calendars, catalogues, and indexes which are printed, or those existing in manuscript in the various branches of the record office. The best work of general reference is the 'Report of the Select Committee in 1800,' from which we have taken a brief analytical list of the subjects to which the public records relate. Though this list is not altogether what is to be desired, it is the best within moderate limits that we know of, and is sufficient to prove that there is perhaps no branch of the public administration of our country which is destitute of its authentic memorials. It was compiled by Mr. Luders, and is printed in the above Report.

England.

I. *The King, Royal Family, and Household.*

1. The King. 2. The Queen. 3. The Prince of Wales. Household. Privy Seals and Correspondence. Principality of Wales. Duchy of Cornwall. 4. Custos Regni, Lieutenant, Protector, Regent, Lord Justices. 5. Household. 6. The King's Chamber.

II. *The Royal Councils.*

1. Parliament. The House of Lords. The House of Commons. 2. Privy Council.

III. *The Royal Prerogative.*

1. In Ecclesiastical Affairs. Before and after the Reformation. Proceedings of the Commonwealth. 2. In Civil Affairs. General Administration of the Realm. Honours and Offices. Trade and Coin. 3. In Military and Naval Affairs. 4. In Foreign Affairs.

IV. *The Royal Revenues.*

1. Ordinary. Land Revenues. Casual Revenues. 2. Extraordinary.

V. *Courts of Justice.*

1. Of Abolished or Obsolete Jurisdiction. Curia Regis. Placita de Assisis. Placita Itineraria. Placita Forestæ. Placita Coronæ. Placita Aulæ. Placita de Quo Warranto. Star Chamber Proceedings. Court of Requests. Court of Wards and Liveries. Court of Augmentations. Surveyor-General's Court. Court of Chivalry: namely, Constable and Marshal. 2. Of Occasional Jurisdiction. Special Commissions. Court of Judicature for determining Differences after the Fire of London. High Court of Justice. 3. Of Established Jurisdiction. Chancery. Its ordinary and Extraordinary Jurisdiction. King's Bench. Pleas of the Crown and in Civil Suits. Common Pleas. Exchequer of Account—The Queen's Remembrancer's Office. The Lord Treasurer's Remembrancer's Office. Exchequer of Receipt—Tellers, Tally Court, Auditor or Tally Writer, Pell Office, Auditors of Imprest, Commissioners for auditing the Public Accounts. Exchequer of Pleas and of Error. Marshalsea and Palace Courts. Session of Oyer and Terminer and Gaol Delivery for London, and Gaol Delivery for Middlesex. Great Sessions of Wales. Duchy of Lancaster. Counties Palatine. Stannary Courts. Cinque Ports. Commissioners of Sewers. Quarter-Sessions and Clerks of the Peace. Maritime Courts.—Admiralty Instance Court, Admiralty Prize Court, Court of Appeal in Prize Causes. Ecclesiastical Jurisdiction—Archiepiscopal, Episcopal, Appellate Jurisdiction, Deans and Chapters. Courts for offences in India.

VI. *Universities and Colleges, Schools, &c.*

1. Universities and Colleges. 2. Royal Schools, Chauntries, Hospitals, Colleges, Free Chapels, Fraternities, and Guilds.

VII. *Alienation of Private Property.*

SCOTLAND.

1. *The King.*

Title, Great Seal, Privy Seal, Signet, Chancery, Revenues, and Expenses. Acts of Civil Government. Ecclesiastical Government. 2. Parliament. 3. Privy Council. 4. General Registers. 5. Courts of Justice. Court of Session. Justiciary Court. Court of Exchequer. Admiralty Court. Commissary Courts. Court of Teind. Sheriff Court. 6. Universities.

IRELAND.

The Principal Record Repositories in Dublin are the *Bermingham Tower*, which contains Plea Rolls, Pipe Rolls, Summonisters' Rolls, Sheriffs' Tot Rolls, &c.; the *Parliamentary Record Office;* the *Rolls Office;* the Statute Rolls from Hen. V. to the Union; Patent and Close Rolls from 31 Ed. I. to the present time; Inquisitions post Mortem; Fiants from 21 Hen. VIII. to the present time: Decree Rolls; Recognisance Rolls from 21 Hen. VIII.; the *Chief Remembrancer's Office,* Memoranda Rolls from 6 Ed. I. to the present time; the *Auditor-General's Office,* Rolls of Public Accounts from Hen. VIII.; the Receiver-General, Vice-Treasurer's, Pell's, and Chamberlain's Books, the Debenture Exchequer Bills, and other Loan Books, the Vouchers of Public Accounts, the Collector's Accounts from every district in Ireland; the Quit-Rent Receipt Books, the Sheriffs' Accounts, with some Ancient Accounts of the Hanaper, First Fruits, Farmers of Revenue, Subsidies, Poll Tax, &c. The *Prerogative Office;* the *First Fruits Office; Surveyor-General's Office.* (*Reports of the Commissioners on the Public Records of Ireland.*)

The most important Public Records may be enumerated as follows:—

Great Roll of the Exchequer, from Hen. II., 1154—1833.

Exchequer—Lord Treasurer's, and Pipe Office, 2 Hen. II.—1833; with Memoranda Rolls, originalia Rolls, and various other enrolments, 1 Hen. III.—1833.

Exchequer—King's Remembrancer—Memoranda Rolls, and various classes of the Exchequer equity business, 1 Hen. III.—1841, when the business was transferred to the Court of Chancery.

Exchequer—First Fruits and Tenths, certificates of Institutions to Livings, 1558—present time; and various other classes, Hen. VIII. to present time.

Exchequer—Court of Augmentations, Ministers' account of Crown lands, and lands in the hands of the Crown, 27 Hen. VIII.,—1 Mary, when the Court was abolished.

Exchequer—Ministers' Accounts, 1 Mary—Chas. II.; and various other classes, Hen. VIII.—1649.

Exchequer—Pleas or Judgment Rolls, and various classes of Records of the Court, 1293 to present time; from 1830, including the business of the abolished Welsh Courts.

Comptroller's or Chancellor's Roll, 11 Hen. II—1833 (now deposited in the British Museum).

Rotuli Curiæ Regis, Ric. I., 1194—Hen. III., 1216.

Fines, Concords, Writs of Covenant, Feet of Fines, &c., 25 Hen. II., 1179—Wm. IV., 1833.

Charter Rolls, John, 1199—Hen. VIII., 1509.

Norman Rolls, John, 1200—Hen. V., 1412.

Patent Rolls, John, 1201—present time.

Close Rolls, John, 1204—Geo. II., 1727.

Liberate Rolls, John, 1200—Edw. IV., 1460-1.

Fine Rolls, John, 1204—Chas. I., 1625.

French Rolls, Hen. III., 1242—Edw. IV., 1460-1.

Gascon Rolls, Hen. III., 1242—Hen. VI., 1422.

Scotch Rolls, Edw. I., 1291—Edw. IV., 1460-1.

Roman Rolls, Edw. I., 1305—Edw. IV., 1460-1.

Statute Rolls (afterward the Parliament Rolls), Edw. I., 1277—Edw. IV., 1460-1.

Rolls of Parliament, Edw. I., 1272—Ric. III., 1483; Statutes, Hen. VII., 1485 to present time.

Petitions in Parliament, Edw. I., 1272—Edw. IV., 1460.

Journals of the House of Lords, Hen. VIII., 1509 to present time.

Journals of the House of Commons, Hen. VIII., 1509.

Summons and Returns to Parliament, Edw. I., 1288—Hen. VI., 1422; 33 Hen. VIII.—present time.

Original Acts of Parliament, 12 Hen. VII.—present time.

Inquisitiones post Mortem, or Escheats, Hen. III., 1216—Chas. I., 1625.

Inquisitiones ad quod damnum, Edw. II., 1307—Hen. VI., 1422.

Coronation Rolls, Edw. II., 1307—(series imperfect)—Geo. II., 1727.

Treaty Rolls (irregular series), Edw. V., 1483—James II., 1684-5.

Confirmation Rolls, Ric. III., 1483—Commonwealth, 1649.

Dispensation Rolls, 37 Eliz.—Geo. II., 1727.

Rolls of Pardons, Ric. III., 1483—Eliz., 1558.

Judgment or Decree Rolls of Chancery, 25 Hen. VIII.—present time.

Court of Chancery, various classes, from John to the present time.

Surrender and Specification Rolls, Chas. II., 1648-9—present time.

Privy Seals and Signet Bundles, Bills, and Writs, Edw. I., 1272—present time.

Signed Bill Bundles, Hen. VII., 1485—present time.

King's Bench Judgments, &c. inrolled, Edw. I., 1272—present time.

King's Bench—Crown side, Curia Regis and Coram Rege, or Crown Rolls, 5 Ric. I., to present time; Controlment Rolls, 1 Edw. III.—1844; various other classes from James I. to present time.

King's Bench—Plea side; before 1702, see Coram Rege; various classes of Records of the Court, from 1700 to present time.

Common Pleas—Plea or Judgment Rolls, and Placita terræ, and various classes of Records of the Court, Hen. III. to present time; for prior records see Curia Regis.

Pleas of the Forest, Hen. III., 1216—James II., 1684-5.

Miscellaneous Records of the King's Remembrancer, Ric. I., 1189—Geo. III., 1760.

Placita de Assisis, 6 Ric. I.—Edw. V., 1483.

Court of Wards and Liveries, Hen. VIII.—Chas. II., when the Court was abolished.

Star Chamber Court—3 Hen. VII.—16 Chas. I., when it was abolished.

Wales—various Courts, abolished 1830; various classes, Hen. III.—1830.

The preceding list exhibits generally, with a few exceptions hereafter noticed, the commencement of the chief and most valuable of our national records, and the periods over which they extend, from the time of Richard I., the boundary of "legal memory."

In the above list we have not included Domesday Book, the choicest of all our record treasures, and the corner-stone of our topographical history. The record itself has been most faithfully printed, and copiously described by Sir Henry Ellis. [DOMESDAY BOOK.] There are two abridgments of Domesday Book among the exchequer records, made probably about the time of Henry III. Subsequent territorial surveys, the Hundred Rolls, Extenta Manerii, Testa de Nevill, Pope Nicholas' Taxation temp. Edw. I., the Domesday of Wales, and Nonæ Rolls temp. Edw. III., King Henry VIII.'s Surveys, and Parliamentary Surveys of the Commonwealth, are excluded, because they form no consecutive series like the above.

The Great Roll of the Exchequer, or Pipe Rolls, or Rotuli Annales, being yearly accounts of the king's revenue, are conjectured to have begun with the Conqueror. Some evidence exists to establish that they probably extended over the whole reign of Henry I., though we know at present but of a single roll, the thirty-first year of that reign, which the Record Commission published under the editorship of Mr. Hunter. Excepting the rolls for the 1st of Henry III. and 7 Henry IV., the series from the 2nd of Henry II. is complete. Madox speaks of them as "Recorda omnium quæ in Archivis Regis usquam me memini, splendidissima, post Rotulum censualem quem Librum Domesday vocant; quin ei æquiparanda."

The series of Fines, being records of the transfer of lands, &c., extends unbroken, and almost unchanged in form, from the 25 Henry II. to the end of the year 1833, when this species of conveyance was abolished. [FINES.] Since the 16 Edward I. they have been delivered from time to time into the 'treasury' of the exchequer. Those in the Chapter-house and those lately kept by the Custos Brevium of the Common Pleas will shortly be united, and will present a series of records, like the Pipe Rolls and Rolls of the Curia Regis, unrivalled in all Europe. The Cartæ Antiquæ, formerly in the Tower, are transcripts of charters descending from the Saxon times to Henry III. They are hardly to be considered as part of the splendid series of chancery rolls commencing in King John's reign. In noticing the chancery rolls it is quite superfluous to do more than refer the reader to the prefaces which Mr. Thomas Duffus Hardy has attached to his editions of the earliest close and patent rolls. If we were to continue to particularise documents of age and interest, such as the Norman pipe-roll of Henry I., the 'Rotulus de Dominabus, temp. Henry II.' (which was printed by Mr. Stacey Grimaldi, in 1830), the Red Book of the Exchequer, containing the laws of the Conqueror and those ascribed to Henry I. (which has been fully catalogued by Mr. Hunter, in the 'General Report of Commissioners on Public Records,' 1837, p. 165), the Misæ and Præstita rolls of King John, or the Magnæ Chartæ of our kings, which were not inrolled in a systematic series until 1278, we should never conclude the subject. We therefore refrain from further specifications, and conclude this article with lists of the various publications lately issued by the Record Commissioners, and at present proceeding under the direction of the Right Honourable Sir John Romilly.

1. Domesday Book: seu Liber censualis Willielmi Primi, Regis Angliæ.
    Domesday Book, 2 vols. folio, 1783.
    Additamenta, consisting of the Exon Domesday, Inquisitio Eliensis, the Winton Domesday and the Boldon Book, and Indices, 2 vols. folio, 1816.

2. Statutes of the Realm, 9 vols. fol.; Alphabetical Index, 1 vol.; Chronological Index, 1 vol.: in all eleven volumes.

3. Fœdera, Conventiones, Litteræ, et cujuscunque generis Acta Publica, inter reges Angliæ, et alios quosvis Imperatores, Reges, Pontifices, Principes vel Communitates (being a new edition of Rymer's Fœdera).

4. Calendarium Rotulorum Patentium in Turri Londinensi (from John to Edward IV.), 1 vol. fol.

5. Calendarium Rotulorum Chartarum et Inquisitionum ad quod damnum (from John to Henry VI.), 1 vol. fol.

6. Calendarium Inquisitionum ad quod damnum (from 1 Edward II. to 38 Henry VI.).

7. Placitorum in domo Capitulari Westmonasteriensi asservatorum abbreviatio, temporibus regum Ric. I., Johannis, Hen. III., Edw. I. et Edw. II., 1 vol. fol.

8. Testa de Nevill; sive liber Feodorum in Curia Scaccarii, temp. Hen. III. et Edw. I., 1 vol. fol.

9. Rotulorum Originalium in curia Scaccarii abbreviatio temporibus regum Hen. III., Edw. I., II., et III., 1 vol. fol.

10. The Parliamentary Writs, and Writs of Military Summons; together with the Records and Muniments relating to the suit and service due and performed to the King's High Court of Parliament and the Councils of the Realm, or affording evidence of attendance given at Parliaments and Councils, vol. i.; vol. ii. divisions 1 and 2 and 3, fol.

11. Rotuli Hundredorum, temp. Hen. III. et Edw. I. in Turri Lond., et in Curia Receptæ Scaccarii Westm. asservati, 2 vols. fol., 1812.

12. Placita de Quo Warranto, temporibus Edward I., II., et III., in Curia Scaccarii Westm. asservata, 1 vol. fol., 1818.

13. Calendarium Inquisitionum post Mortem, sive Escaetarum, 4 vols. fol. (from Henry III. to Edward IV.).

14. Nonarum Inquisitiones in Curia Scaccarii temp. Regis Edwardi III., 1 vol. fol.

15. Taxatio Ecclesiastica Angliæ et Walliæ, Auctoritate P. Nicholai IV., circa A.D. 1291, 1 vol. folio.

16. Valor Ecclesiasticus, temp. Henry VIII., Auctoritate Regia institutus, 6 vols., folio.

17. Calendars of the Proceedings in Chancery in the Reign of Queen Elizabeth; to which are prefixed Examples of earlier Proceedings in that Court, namely, from the Reign of Richard II. to that of Queen Elizabeth inclusive, from the originals in the Tower, 3 vols., folio.

18. Ducatus Lancastriæ Pars Prima:—Calendarium inquisitionum post Mortem, &c., temporibus Regum Edw. I., Edw. III., Ric. II., Hen. V., Hen. VI., Edw. IV., Hen. VII., Hen. VIII., Edw. VI., Regin. Mar., Phil. et Mar., Eliz., Jac. I., Car. I.

Pars Secunda:—A Calendar to the Pleadings, &c., in the reigns of Henry VII., Henry VIII., Edward VI., Queen Mary, Philip and Mary, and Elizabeth, 3 vols., fol.

19. A Catalogue of the Manuscripts in the Cottonian Library deposited in the British Museum, I vol., folio, 1802.

20. A Catalogue of the Harleian Manuscripts in the British Museum, 4 vols., fol., 1808-1812.

21. A Catalogue of the Lansdowne Manuscripts, 1 vol., fol.

22. The Acts of the Parliament of Scotland, 11 vols.; from 1424 to 1707.

23. Registrum Magni Sigilli Regum Scotorum, in Archivis Publicis asservatum, A.D. 1306-1424, 1 vol. fol., 1814.

24. Rotuli Scotiæ in Turri Londinensi, et in Domo Capitulari Westmonasteriensi asservati, 2 vols., fol.

25. Inquisitionum ad Capellam Domini Regis retornatarum quæ in Publicis Archivis Scotiæ adhuc servantur Abbreviatio, 3 vols., fol.

26. A General Introduction to Doomsday Book, 2 vols., 8vo.

27. Rotulus Litterarum Patentium 7 John: Transcripta Litt. Pat. Hiberniæ, temp. Hen. V. and VI. Placita 52 Hen. III., 8vo.

28. Rotuli Litterarum Clausarum ab anno 1204 ad annum 1224, 1 vol.

29. Rotuli Litterarum Patentium A.D. 1201-1216, fol.

30. The Chancellor's Roll, or Antigraph of the Great Roll of the Pipe, 3 John, 8vo.

31. Rotulus Magnus Pipæ de anno 31 Henrici I., commonly called the Roll of Stephen, 8vo.

32. Proceedings and Ordinances of the Privy Council in the reigns of Richard II., Henry IV., V., VI., 7 vols., 8vo.

33. Rotuli Normanniæ: John and Henry V., 8vo.

34. Excerpta e Rotulis Finium; Henrici III., 2 vols., 8vo.

35. Rotuli de Oblatis et Finibus; John, 1 vol., 8vo.

36. Fines sive Pedes Finium, sive finales Concordiæ in Curiâ Domini Regis, A.D. 1195-1214, 8vo.

37. Rotuli Curiæ Regis Ric. I. et Johan, 2 vols., 8vo.

38. An Account of the most important Records of Great Britain, by C. P. Cooper, 2 vols., 8vo.

39. Selections from the Miscellaneous Records of the King's Remembrancer of the Exchequer, 8vo.

40. Ancient Inventories and Calendars of the Treasury of the Exchequer, from Edward III. to Henry VIII., 3 vols., 8vo.

41. Documents elucidating the Ancient History of Scotland, Alexander III. to Robert I., 1 vol., 8vo.

42. The Charter Rolls of John, 1 vol., fol.

43 Ancient Laws and Institutes of England, comprising laws enacted under the Anglo-Saxon kings from Æthelbert to Canute, with an English translation of the Saxon; the laws called Edward the Confessor's; the laws of William the Conqueror; and those ascribed to Henry I. Also Monumenta Ecclesiastica Anglicana, from the 7th to the 11th century; and the ancient Latin version of the Anglo-Saxon Laws, 1 vol., fol., 1840, and

44. Monumenta Historica Britannica, 1 vol., fol., 1848.

The printing of other works was in progress when the Record Commission dropped. See 'Report on the Record Commission, App.,' p. 782.

State Papers preserved in the State Paper Department of the Public Record Office, published in imp. 8vo, price 15s. each volume.

Calendar of State Papers, Domestic series, of the Reigns of Edward VI., Mary, Elizabeth, 1547–1580. Edited by Robert Lemon, Esq., F.S.A. 1856.

Calendar of State Papers, Domestic Series, of the Reign of James I. Edited by Mary Anne Everett Green. 1857–1859. In 4 vols., from 1603 to 1625.

Calendar of State Papers, Domestic Series, of the Reign of Charles II. Edited by Mary Anne Everett Green. 1860. A second volume is in the press.

Calendar of State Papers, Domestic Series, of the Reign of Charles I. Edited by John Bruce, Esq., V.P.S.A. 1858–1859. Three vols.; a fourth volume is in the press.

Calendar of State Papers relating to Scotland. Edited by Markham John Thorpe, Esq., Oxford. 1858. In 2 vols., from 1509 to 1587.

Calendar of State Papers relating to Ireland, 1509–1573. Edited by H. C. Hamilton, Esq., F.S.A. 1860. Vol. II. is in the press.

Calendar of State Papers, Colonial Series. Edited by W. Noël Sainsbury, Esq. 1860. A second volume is in the press; as also are—

Calendar of State Papers of the Reign of Henry VIII. Edited by the Rev. J. S. Brewer, M.A.

Calendar of State Papers, Foreign Series, of the Reign of Edward VI. Edited by W. B. Turnbull, Esq.

There have been also published, in royal 8vo, price 8s. 6d. per volume, the Chronicles and Memorials of Great Britain and Ireland during the Middle Ages.

1. The Chronicle of England, by John Capgrave. Edited by the Rev. F. C. Hingeston, M.A.

2. Chronicon Monasterii de Abingdon. Vols. I. and II. Edited by the Rev. J. Stevenson, M.A.

3. Lives of Edward the Confessor. I.—La Estoire de Seint Aedward le Rei. II.—Vita Beati Edvardi Regis et Confessoris. III.—Vita Æduuardi Regis qui apud Westmonasterium requiescit. Edited by H. R. Luard, M.A.

4. Monumenta Franciscana; scilicet, I.—Thomas de Eccleston de Adventu Fratrum Minorum in Angliam. II.—Adæ de Marisco Epistolæ. III.—Registrum Fratrum Minorum Londoniæ. Edited by the Rev. J. S. Brewer, M.A.

5. Fasciculi Zizaniorum Magistri Johannis Wyclif cum Tritico. Ascribed to Thomas Netter, of Walden, Provincil of the Carmelite

Order in England, and Confessor to King Henry the Fifth. Edited by the Rev. W. W. Shirley, M.A.

6. The Buik of the Croniclis of Scotland; or, A Metrical Version of the History of Hector Boece; by William Stewart. Edited by W. B. Turnbull, Esq. In 3 volumes.

7. Johannis Capgrave Liber de Illustribus Henricis. Edited by the Rev. F. C. Hingeston, M.A.

8. Historia Monasterii S. Augustini Cantuariensis, by Thomas of Elmham, formerly Monk and Treasurer of that Foundation. Edited by C. Hardwick, M.A.

9. Eulogium (Historiarum sive Temporis), Chronicon ab Orbe condito usque ad Annum Domini 1366; a Monacho quodam Malmesbiriensi exaratum. Vol. I. Edited by F. S. Haydon, Esq., B.A. Two other volumes are in the press.

10. Memorials of King Henry the Seventh: Bernardi Andreæ Tholosatis de Vita Regis Henrici Septimi Historia; necnon alia quædam ad eundem Regem Spectantia. Edited by J. Gairdner, Esq.

11. Memorials of Henry the Fifth. I.—Vita Henrici Quinti, Roberto Redmanno auctore. II.—Versus Rhythmici in laudem Regis Henrici Quinti. III.—Elmhami Liber Metricus de Henrico V. Edited by C. A. Cole, Esq.

12. Munimenta Gildhallæ Londoniensis; Liber Albus, Liber Custumarum, et Liber Horn, in archivis Gildhallæ asservati. Vol. I., Liber Albus. Vol. II. (in Two Parts), Liber Custumarum. Edited by H. T. Riley, Esq., M.A.

13. Chronica Johannis de Oxenedes. Edited by Sir H. Ellis, K.H.

14. A Collection of Political Poems from the Accession of Edward III. to the Reign of Henry VIII. Vol. I. Edited by T. Wright, Esq., M.A. A Collection of Political Prose for the same period is also in the press.

15. The 'Opus Tertium' and 'Opus Minus' of Roger Bacon. Edited by the Rev. J. S. Brewer, M.A.

16. Bartholomæi de Cotton, Monachi Norwicensis, Historia Anglicana (A.D. 449–1298). Edited by H. R. Luard, M.A.

17. The Brut y Tywysogion, or, The Chronicle of the Princes of Wales. Edited by the Rev. J. Williams ab Ithel.

18. A Collection of Royal and Historical Letters during the Reign of Henry IV. Vol. I. Edited by the Rev. F. C. Hingeston, M.A. A second volume is in the press.

19. The Repressor of over much Blaming of the Clergy. By Reginald Pecock, sometime Bishop of Chichester. Vols. I. and II. Edited by C. Babington, B.D.

20. The Annales Cambriæ. Edited by the Rev. J. Williams ab Ithel.

In the Press.

Ricardi de Cirencestria Speculum Historiale de Gestis Regum Angliæ. (A.D. 447–1066). Edited by J. E. B. Mayor, M.A.

The Anglo-Saxon Chronicle. Edited by B. Thorpe, Esq.

Le Livere de Reis de Brittanie. Edited by J. Glover, M.A.

Recueil des Croniques et Anchiennes Istories de la Grant Bretaigne a present nomme Engleterre, par Jehan de Waurin. Edited by W. Hardy, Esq.

The Wars of the Danes in Ireland: written in the Irish language. Edited by the Rev. Dr. Todd.

Original Letters and Papers illustrative of the History of England during the Fifteenth Century. Edited by the Rev. J. Stevenson, M.A.

A collection of Sagas and other Historical Documents relating to the Settlements and Descents of the Northmen on the British Isles. Edited by George W. Dasent, Esq., D.C.L.

The Works of Giraldus Cambrensis. Edited by the Rev. J. S. Brewer, M.A.

Letters and Papers of the Reigns of Richard III. and Henry VII. Edited by James Gairdner, Esq.

Munimenta Gildhallæ Londoniensis; Liber Albus, Liber Custumarum, et Liber Horn, in Archivis Gildhallæ asservati. Vol. III. Translations from the Anglo-Norman portions of the Liber Albus; Appendix; Glossaries; and Index. Edited by H. T. Riley, Esq., M.A.

Descriptive Catalogue of Manuscripts relating to the Early History of Great Britain. Edited by T. Duffus Hardy, Esq.

In progress.

Historia Minor Matthæi Paris. Edited by Sir F. Madden.

Letters and Treatises of Bishop Grossetete, illustrative of the Social Condition of his Time. Edited by the Rev. H. R. Luard, M.A.

Chronicon Abbatiæ Eveshamensis, Auctoribus Dominico Priore Eveshamiæ et Thoma de Marleberge Abbate, a Fundatione ad Annum 1213, una cum Continuatione ad Annum 1418. Edited by the Rev. W. D. Macray, M.A.

A Roll of the Irish Privy Council of the 16th year of the Reign of Richard II. Edited by the Rev. James Graves.

Polychronicon Ranulphi Higdeni, with Trevisa's Translation. Edited by C. Babington, B.D.

RECOVERY, COMMON. A common recovery was a judgment in a fictitious suit, in which the tenant of the freehold was the defendant; and the judgment was given in consequence of default made by the person who was last vouched, that is, summoned to warranty in such suit. It was used for the purpose of barring estates tail and all remainders and reversions expectant thereon.

A common recovery was in the form of a judgment obtained in a real action, and accordingly the mode of proceeding was the same as in an action not fictitious. The plaintiff in the action, or demandant, who sought to recover the lands, sued out a writ or præcipe, as it was called, from the words of the writ (Præcipe A. the tenant, quod juste, &c. reddat B. the lands in question) against the person who had the freehold of the estate, and who was called the tenant to the præcipe. He appeared to the writ; but instead of defending his title, he vouched (vocavit) some other person who was supposed to be bound to warrant the tenant's title, and he prayed that the person so vouched (the vouchee) might defend the title so warranted, or that, if he could not, he might give the tenant lands of equal value with those which he might lose by failure of the warranty. The vouchee, having appeared, undertook the defence of the tenant's title, but he purposely failed to do so, and on his default the court gave judgment, which was that the demandant or recoverer should recover the lands against the tenant, and that the tenant should recover against the vouchee lands of equal value. Such lands were called the recompense or recovery in value. By the first judgment the demandant obtained the fee simple of the estate. The whole proceeding being a fiction, it was usual to make the common crier of the Court of Common Pleas the vouchee, who was hence called the common vouchee. This proceeding was called recovery with single voucher; but there might be recovery with double or treble voucher, in which case judgment was given against the several vouchees. Where an estate tail was to be barred, there was double voucher, the tenant in tail conveying an estate of freehold to some person, against whom the demandant brought the præcipe, who then vouched the tenant in tail, who vouched over the common vouchee, who of course made default, and judgment was accordingly given for the demandant against the tenant to the præcipe, for the tenant to the præcipe against the tenant in tail, and for him against the common vouchee.

On judgment being given, a writ of *habere facias seisinam* was sued out, which, though not executed, was returned as if it had been, and the recovery was then complete.

A defect in any one of the proceedings might vitiate the recovery. One of these circumstances of the greatest practical importance was the making a good tenant to the præcipe; for unless the person against whom the writ was brought was actual tenant of the freehold, there could be no good recovery. It was however sufficient if he acquired the freehold at any time before judgment was given in the suit; and by 14 Geo. II., c. 20, § 6, it was sufficient if he acquired the freehold after judgment and the award of the writ of execution.

It was usual for the tenant in tail to be vouched in recovery to bar estates tail, because the validity of the recovery was founded on the doctrine that the estate which the tenant in tail obtained by virtue of the warranty in lieu of that which he lost by the vouchee's default, would descend to the heirs in tail, just as the estate would have done which the tenant in tail had lost. It is true that the recompense could not extend to the person entitled to the reversion, nor to contingent interests; but this defect, which would have been fatal if the transaction had been real, was never considered to impair the efficacy of the fictitious proceeding. And it was a settled principle that the estate obtained by way of recompense would only follow the course of descent of that estate of which the tenant in tail was seised at the time of the recovery; and therefore if the tenant in tail at the time of the recovery was not seised of an estate tail according to the form of the original gift, the recompense in value would descend according to the estate which he had at the time of the recovery, and not according to the original gift; and consequently those who claimed under the original gift would not be barred because they obtained no recompense in value. It might happen in various ways that the estate which the tenant in tail had at the time of the recovery was not the estate tail according to the original gift. To prevent this inconvenience, the tenant in tail gave an estate of freehold to some person in order to make him a good tenant to the præcipe. This was done in various ways, but generally by bargain and sale enrolled, or by lease and release. The instrument which transferred the estate of freehold generally contained the declaration of the uses of the recovery, as hereinafter mentioned. The action being brought against the tenant to the præcipe, he vouched the tenant in tail, who vouched over the common vouchee. As the tenant in tail confessed the warranty, and undertook the defence of the action, he was considered to submit all his rights in the land to the effect of the recovery, which was called a recovery with double voucher.

A common recovery was generally suffered in the Court of Common Pleas; but common recoveries of lands in the counties palatine of Durham and Lancaster were suffered in the respective courts of those counties. A recovery of lands held in ancient demesne was suffered in the courts of the manors of which such lands were held; and in many manors a recovery might be suffered in the customary courts of such manors of which the copyholds were parcel.

The effect of a common recovery differed in several respects from that of a fine. A fine was originally introduced as a mode of alienation by record, and its effect in barring entails was owing to the statutes 4 Hen. VII., c. 24, and 37 Hen. VIII., c. 19, which were not made till several centuries after the introduction of fines. A common recovery had no absolute effect after a fixed number of years, as a fine had; but inasmuch as the recoveror acquired an estate in fee simple, it had effects very different from those of a fine. A common recovery duly suffered defeated all the remainders and reversions expectant on the estate tail, and also all shifting uses and executory devises expectant upon it, provided the recovery was suffered before the contingency happened on which the executory devise was to take effect. A fine had the effect of destroying the estate tail by converting it into a determinable fee. Accordingly if the tenant in tail who had the immediate remainder or reversion in fee barred his estate tail by a fine, he acquired a base fee, which was merged in the remainder or reversion, which thus became an estate in possession, and subject to all the charges and estates made and created by the person from whom the tenant in tail derived his remainder or reversion. Besides this, it would be necessary for such person on any occasion of selling his land, to make out his title to the remainder or reversion. A common recovery operated by enlarging the estate tail into a fee, and thus absolutely destroying all remainders and reversions, but it confirmed all prior estates or charges made by the tenant in tail who suffered the recovery. Thus if a tenant in tail made a lease not permitted by the stat. 32 Henry VIII., or acknowledged a judgment, and then suffered a common recovery, this would be a confirmation of those charges, which, if there had been no recovery, would have had no effect against the issue in tail.

The origin of recoveries is referred to the decision in Taltarum's case 12 Edw. IV., in which, though it was declared that the estate tail in question was not barred by the recovery suffered, the reason that was given for the decision admitted that it might have been barred by a recovery. In Taltarum's case, the tenant who suffered the recovery was not seised of the estate tail under which the issue in tail claimed, but he was seised of a different estate at the time of the recovery being suffered.

Recoveries were impeachable for various reasons, such as defect of jurisdiction in the court in which they were suffered, informality in the proceedings, and the want of a good tenant to the præcipe.

The immediate object of the recovery, as above observed, was to give an estate in fee simple to the recoveror; but the ultimate object was to commonly settle the estate to new uses, which were generally declared by the instrument which gave the estate of freehold to the tenant to the præcipe.

By 3 & 4 Will. IV., c. 74, fines and recoveries were abolished, formal defects in those already levied or suffered were cured, and a simple mode of assurance substituted for the barring of an estate tail by deed enrolled in the court of chancery within six calendar months after its execution.

RECRUITING is the act of raising men for the military or naval service, either to augment the numerical strength of an army or fleet by new levies, or to make good the complement of any regiment or ship. The term may be used when men are obtained in any of the ways which the customs of nations have sanctioned, or the necessities of certain times may have required: but among military men it is employed when officers, especially appointed for the purpose, engage men by the offer of bounties to enter as private soldiers into particular regiments. The officers, commissioned and non-commissioned, while so employed, are said to be on the recruiting service; but the actual engaging of men as recruits is called enlistment; and the laws relating to this subject have been already noticed. [ENLISTMENT.]

Formerly private persons were allowed to enlist men for the army in any way that they might think best; but these having sometimes adopted, in order to procure recruits, violent and illegal means by which the public indignation was excited, the government in 1802 took the management of the recruiting department into its own hands; and now, by a clause in the Mutiny Act, any person advertising or opening an office for recruits without authority in writing from the adjutant-general is liable to the penalty of twenty pounds.

In order to produce uniformity in the system of recruiting, and to ensure the employment of legal means only in obtaining men, the supreme control of this branch of the military service was vested in the adjutant-general of the army, and both Great Britain and Ireland were divided into several recruiting districts. To each of these was appointed an inspecting field-officer; an adjutant, whose duty it is to ascertain, in respect of stature and bodily strength, the fitness of any recruit for the service; a paymaster, and a surgeon, the latter of whom is to report concerning the health of the recruit. Under the inspecting field-officer there are several regimental officers, who are stationed in the principal towns of the different districts in order to superintend the non-commissioned officers appointed to receive the applications of the persons who may be desirous of entering the service.

England and Scotland are divided into six recruiting districts, the head-quarters of which are respectively at York, Liverpool, Bristol, London, Glasgow, Edinburgh. Ireland is divided into three recruiting districts, of which the head-quarters are Belfast, Dublin, and Cork. Superintending officers are stationed at the various important towns in the district according to the exigencies of the service.

In order to procure recruits, a sergeant or other non-commissioned officer mixes, in country places, with the peasantry at their times of recreation; and, in towns, with artisans who happen to be unemployed, or who are dissatisfied with their condition; and, by address in representing whatever may seem agreeable in the life of a soldier, or by the allure of a bounty, occasionally induces such persons to enter the service.

The reports concerning the fitness of a recruit for military service are finally submitted for approval to the inspecting field-officer of the district, except when the distance of the head-quarters from the place where the recruit is enlisted is such that it would be more convenient to send the latter to the depôt of the regiment to which he is to belong: in that case the officer commanding at the depôt is especially authorised to sanction them.

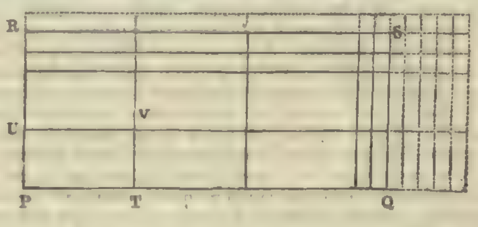
Officers employed on the recruiting service are not allowed to interfere with one another in the performance of their duties; particularly, no one is permitted to use any means in order to obtain for his own party a man who has already taken steps by which he may become engaged to another.

RECTANGLE (or right angled), the name given to any figure of which all the angles are right angles. Hence the figure having as many right angles as sides in the sum of its angles, must be foursided; for none but a foursided figure has the sum of its angles equal to four right angles. It is unnecessary to give a diagram of the most common of all the forms of art; the page of this book may serve as an instance.

The properties of the rectangle, to which it owes its importance in a mathematical point of view, consist of one which it shares in common with all parallelograms, and one which marks it as the most simple of parallelograms. Every parallelogram, and the rectangle among the rest, may be divided in an infinite number of ways into parallelograms having the same angles as the original parallelogram; and if any parallelogram be divided into others by lines drawn parallel to one only of the sides, the smaller parallelograms bear to the whole the same ratios which their several bases bear to the whole base. Also the area of a rectangle may be immediately deduced from nothing but the length of its two sides. If as a superficial unit we choose a rectangle having the sides A and B, it may immediately be told how many times and parts of times any other rectangle contains the unit. Measure one side, and see how many times it contains A (say $2\frac{2}{3}$); measure the other side, and see how many times it contains B (say $3\frac{2}{7}$); then the product of $2\frac{2}{3}$ and $3\frac{2}{7}$, or

$$\frac{8}{3} \times \frac{23}{7}, \text{ or } \frac{184}{21}, \text{ or } 8\,\frac{16}{21},$$

is the number of times which the rectangle to be measured contains the unit rectangle. This may be shown as follows:—



Let PQRS be the rectangle to be measured, and PTUV the unit rectangle, PU being A, and PT being B. The rectangle RQ is so drawn that PR contains $2\frac{2}{3}$ of A, and PQ contains $3\frac{2}{7}$ of B. The whole rectangle is obviously divided into six rectangles of the size of PV: six at the top, each of which is one-third of PV; four on the right, each of which is one-seventh of PV; and four higher up on the right, each of which is the twenty-first part of PV. We have then, on the whole, PV repeated

$$6 + \frac{6}{3} + \frac{4}{7} + \frac{4}{21}, \text{ or } \left(2 + \frac{2}{3}\right)\left(3 + \frac{2}{7}\right) \text{ times.}$$

In practice it is most convenient to make PT and PU equal to one another, and equal to the unit used in measuring lengths. Hence the rule for finding the area of a rectangle is: multiply together the number of linear units in the two sides, and the result is the number of square units (or squares on the linear unit) in the rectangle. This rule is abbreviated as follows: the product of the sides of a rectangle is the area; an abbreviation which often confuses the mind of a beginner, who imagines that two *lines* can be multiplied together [MULTIPLICATION], and that the rectangle, that is, the very shape of the rectangle, is the product; a mistake precisely that of a person who should imagine that the very silver of ten shillings could be multiplied by seven yards of stuff, and that the product could be seventy shillings. Now seven yards of stuff at ten shillings a yard certainly cost as many shillings as there are units in 7 × 10; and a rectangle whose sides are seven and ten feet certainly contains as many square feet as there are units in 7 × 10; but seven feet can no more be multiplied by ten feet than seven shillings by ten yards of silk.

When however given words imply a false proposition, there are two modes of proceeding, either to alter the words or to alter the meaning of the words. If a person should be so accustomed to talk of multiplying concrete quantities together that he cannot avoid it, he must learn to define multiplication as the finding of a fourth proportional to three concrete quantities, the first of which is a concrete unit. If this be the meaning of multiplication, then six yards and three yards can be multiplied together; for as one yard is to three yards so is six yards to eighteen yards, and eighteen yards is the product. But this product is a line, not an area.

The pertinacity with which some writers still persist in calling the product of two lines the area of a rectangle (not only as a practical rule of mensuration, in which it is a desirable mode of expression, but in matters of reasoning) is the result of a long continued habit formed in the first instance by the study of the Greek writers. For though these do not confound the product with the area; yet, on account of the deficiencies of their arithmetical system, they used the area instead of the product, and gave the names of spaces to the results of numbers. Thus the product of two numbers was called plane, that of three equal numbers solid, that of two equal numbers a square, that of three equal numbers a cube, and the difference of two square numbers a gnomon. To these we may add the titles of polygonal, pyramidal, &c. numbers [Numbers, Appellations of], and others which it is needless to mention. All arithmetical propositions were made to take the form of geometrical ones; thus to multiply two numbers was to form the rectangle of two given lines; to divide one number by another was, given the area of a rectangle and one of its sides, to find the other side. We have seen it stated that the word *παραβολή* (parabola) was sometimes used for quotient, and, it was said, in Diophantus. We cannot find it there, though it may be used by the scholiast, whom we have not examined. Adrianus Romanus, in his 'Apologia pro Archimede,' says that the Greeks use *παραβολή* for division as well as *μερισμός*. But most certainly the explanation of the meaning of a parabola, as applied to the well-known curve, comes from some such signification. The term parabola means a thing laid near to or by the side of another; for comparison, for instance, as in the common word *parable*, or for any other purpose. Now in the conic section in question the square on the ordinate being converted into a rectangle one of whose sides is the abscissa, the remaining side (being that which must be laid by the first side before the figure can be drawn, or the *παραβολή*) is always of the same length. If modern writers had applied the term parabola to this remaining side, they would probably have called the curve an isoparabolic section; but the Greeks, who called the curve in which a certain defect is always in the same proportion to the whole by the simple name of defect (ellipse), and one having the same sort of excess by the simple name of excess (hyperbola), called the isoparabolic curve simply a parabola.

Of the geometrical system which pervaded the Greek arithmetic, we have permanently retained only the words square and cube; rectangle was frequently used for product, but rarely at present. These words are the causes of much confusion to students who begin to apply arithmetic to geometry. Thus in algebra the square of a sum is equal to the sum of the squares of the two numbers, together with twice their product. In geometry the square or the sum of two lines is equal to the sum of the squares on the lines, together with twice their rectangle. Those who are not made to see clearly the distinction of these propositions confound them together. A sufficient distinction might be made by a little variation in phraseology: speak of the square *on* a line, and the square *of* a number. Thus 49 is the square of 7: erect two perpendiculars each equal to A B at the two extremities of A B, and joining their other extremities completes the square *on* A B. It is already customary to speak of the rectangle whose contiguous sides are A B and A C, as the rectangle *under* A B and A C.

The second book of Euclid is devoted to the properties of the rectangle, as they arise from subdivision into other rectangles. Some persons advocate what is called the arithmetical proof of these propositions, namely, the substitution of the analogous properties of numbers for those of rectangular spaces. This question must be settled in the same manner as that of Proportion, and the remarks in that article apply. If all pairs of lines were commensurable, no objection could be taken against the rigour of the substitution; but unless a theory of incommensurables, and a modification of the definition of multiplication to suit them, be formally introduced, the method of Euclid is sound, and the substitute for it unsound; though proper enough for the adoption of those who, as explained in the article cited, only wish to become mathematicians to a certain number of decimal places.

RECTIFICATION. [Distillation.]

RECTIFICATION means the finding of a straight line equal in length to an arc of a curve [Arc], and is analogous to the term quadrature, as applied to finding its area; for in like manner as an area is considered to be known when a square equal to it is exhibited, so the length of an arc is known when a straight line equal to it is exhibited.

Of the celebrated problem of the rectification of the circle we have said enough under Quadrature of the Circle, in which article it appears that the rectification gives the quadrature; so that the latter problem was generally attempted through the former.

RECTIFYING. [Distilling.]

RECTOR, RECTORY. [Benefice.]

RECURRING SERIES. By a recurring series is meant one of the form

$$a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + \ldots.$$

ad infinitum, in which the coefficients a_0, a_1, &c. can each be expressed by means of certain preceding coefficients and constants in one uniform manner; and it is usual to consider only such series as will admit of a linear relation (or one in which only first powers of coefficients enter): thus the series

$$1 + x + 4x^2 + 13x^3 + 43x^4 + 142x^5 + \ldots.$$

follows the linear law $a_n = 3a_{n-1} + a_{n-2}$ ($4 = 3.1 + 1$, $13 = 3.4 + 1$, $43 = 3.13 + 4$, &c.), and is what is commonly called a recurring series, though the following—

$$1 + x + 2x^2 + 5x^3 + 29x^4 + 866x^5 + \text{\&c.},$$

in which $a_n = a_{n-1}^2 + a_{n-2}^2$, is equally recurring, according to the definition. The recurrence alluded to is not that of terms, but of method of determining terms; and it would be desirable that the series which are usually called recurring should be *linearly* recurring series, while all in which there is really recurrence (of law) should be called recurring.

Every linearly recurring series is the development of an algebraic function with a rational and integral numerator and denominator, and every such function can be developed into a linearly recurring series. Thus, taking the first series mentioned, in which $a_n = 3a_{n-1} + a_{n-2}$, we have

$$\begin{aligned} a_2 x^2 &= 3a_1 x^2 + a_0 x^2 \\ a_3 x^3 &= 3a_2 x^3 + a_1 x^3 \\ a_4 x^4 &= 3a_3 x^4 + a_2 x^4, \text{ \&c.} \end{aligned}$$

Let s be the sum of $a_0 + a_1 x +$, &c., *ad infinitum*. Then the preceding obviously gives

$$s - a_0 - a_1 x = 3x(s - a_0) + x^2 s;$$

$$\text{or, } s = \frac{a_0 + (a_1 - 3a_0)x}{1 - 3x - x^2}$$

We have here the value of any series in which this law of recurrence prevails for all terms after the second; and it cannot prevail before, since two terms must exist before a third can be expressed. In the case we chose, $a_0 = 1$, $a_1 = 1$, whence the function of which the series was the development is $(1 - 2x) \div (1 - 3x + x^2)$.

Generally, a linear recurring series having the law of recurrence

$$a_n = p_1 a_{n-1} + p_2 a_{n-2} + \ldots. + p_t a_{n-t}$$

is the development of the function

$$\frac{A_0 + A_1 x + A_2 x^2 + \ldots. + A_{t-1} x^{t-1}}{1 - p_1 x - p_2 x^2 - \ldots. - p_t x^t}$$

where $A_0 = a_0$, $A_1 = a_1 - p_1 a_0$, $A_2 = a_2 - p_1 a_1 - p_2 a_0, \ldots.$

$$A_{t-1} = a_{t-1} - p_1 a_{t-2} - p_2 a_{t-3} - \ldots. p_{t-1} a_0,$$

from which the inverse theorem may easily be derived, namely, that

$$\frac{A_0 + A_1 x + A_2 x^2 + \ldots. + A_{t-1} x^{t-1}}{B_0 + B_1 x + B_2 x^2 + \ldots, + B_{t-1} x^{t-1} + B x^t}$$

can be developed into $a_0 + a_1x + a_2x^2 +$ &c., in which the law of recurrence (n not being $< t$) is as follows:—

$$B_0 a_n + B_1 a_{n-1} + B_2 a_{n-2} + \ldots. + B\ a_{n-t} = 0,$$

and the terms up to a_{t-1} are determined by

$$A_0 = B_0 a_0,\ A_1 = B_0 a_1 + B_1 a_0,\ A_2 = B_0 a_2 + B_1 a_1 + B_2 a_0 \ldots.$$

$$A_{t-1} = B_0 a_{t-1} + B_1 a_{t-2} + \ldots. + B_{t-1} a_0.$$

Those who understand the theory of generating functions will see that the generating function can thus be found to the solution of any linear equation of differences. Some use may thus be made of recurring series in various questions of the theory of probabilities; but, generally speaking, this species of series is not of the most useful kind, connected as it is with the rational and integral function of algebra, which is of little application compared with the irrational and transcendental function. [Series.]

The most simple mode of finding the law of the terms of a recurring series is by the solution of the equation of differences, which expresses the relation of the coefficients. This may be verified by decomposing the function which is developed into the series into fractions with denominators of the first degree, according to the common method used in the integral calculus, and expanding each fraction separately.

RECUSANTS are persons who refuse or neglect to attend divine service on Sundays and holidays, according to the forms of the Established Church. Before the Reformation, ecclesiastical censures were directed at different times by provincial councils against those who absented themselves from the services of the church. But the noticing of recusancy in the temporal courts, and probably the use of the term itself, cannot be traced higher than the 16th century. By the 1 Eliz., c. 2, all persons having no lawful excuse are to resort to their parish church upon pain of punishment by the censures of the church, and a forfeiture of twelve pence. By 23 Eliz., c. 1, every person above the age of sixteen years who shall not repair to church, forfeits for every month which he forbears, twenty pounds, and by 35 Eliz., c. 1, if recusants within three months after conviction refuse to submit, they may be compelled to abjure the realm; and if they do not depart, or if they return without licence from the crown, they are guilty of felony, and liable to suffer death.

The law recognised four classes of offenders under the statutes against recusancy:—those who absented themselves from the public service of the church from indifference, irreligion, or dissent, were termed "recusants" simply—after conviction they were styled "recusants convict"; those absentees who professed the Roman Catholic religion were called "Popish recusants"; and those who had been convicted in a court of law of being Popish recusants were called "Popish recusants convict."

The laws against Popish recusants convict were of a very severe character. Blackstone says that these laws were enacted principally *in terrorem*. The truth appears to be that the first penal statutes passed for the purpose of compelling the adherents of the old religion to adopt the new, provoked resistance on their part; and this resistance caused severer enactments, producing in their turn increased resistance, followed by the imposition of still more rigorous penalties.

Popish recusants, in addition to the general penalties enacted against recusants, were disabled from taking lands, either by descent or by purchase, after eighteen years of age, until they renounced their errors. They were bound at the age of twenty-one to register the estates which they had already acquired, and were bound also to register all future conveyances and wills relating to them. They were and are [Quare Impedit] incapable of presenting to any living, or of making a grant of the right of presenting at any avoidance of the benefice. They could not keep or teach any school, on pain of perpetual imprisonment, and for the offence of saying or hearing mass, forfeited certain sums, and were in each case subjected to a year's imprisonment.

Popish recusants convict incurred additional disabilities, penalties, and forfeitures. They were considered as persons excommunicated: could not hold any public office; were not allowed to keep arms; were prohibited from coming within ten miles of London; could bring no action at law or suit in equity; and were not permitted to come to court, or to travel above five miles from home except by licence, upon pain of forfeiting all their goods. Penalties were also imposed in respect of the marriage or burial of the Popish recusant convict, or the baptism of his child, if the ceremony were performed by any other than by a minister of the Church of England. Such a recusant, if a married woman, forfeited two-thirds of her dower or jointure, was disabled from being executrix or administratrix of her husband, and from having any part of his goods, and she might be kept in prison, unless her husband redeemed her at the rate of 10*l.* per month, or by the profits of the third part of all his lands.

Protestant dissenters were relieved from the penalties of recusancy at the Revolution, by the Toleration Act, 1 William & Mary, c. 18. This statute contained a proviso depriving of its benefit any Papist or Popish recusant, or any person that should deny the doctrine of the Trinity. But in 1791, by 31 Geo. III., c. 32, Roman Catholics were exempted from prosecution; and in 1813, by 53 George III., c. 160, the exemption in the Toleration Act, as to persons denying the doctrine of the Trinity, was repealed. The statutes against recusancy, though never enforced, still subsist with respect to persons who, not being Roman Catholics or Protestant dissenters, absent themselves from the service of the Church.

RED. [Calico Printing; Dyeing; Enamel; Painting, House.]

RED LEAD. [Lead: *Red lead.*]

RED OCHRE. [Colouring Matters.]

REDAN is the simplest kind of work employed in field fortification, and it consists generally of a parapet of earth, divided on the plan into two faces, which make with one another a salient angle, or one whose vertex is towards the enemy. Existing alone, the work is capable of making but a feeble defence, since its faces are not defended by any flanking fire; and, being open at the gorge or rear, the enemy may easily enter it in that direction. It can therefore be of use only at an outpost, to afford a momentary cover for troops who are to retire when a superior force advances against them. A redan may however be advantageously placed to cover the head of a bridge, the entrance into a village, or defend the ground in front of some strong redout; a series of them may also be constructed along the front of an army, in order to strengthen the position and cover the artillery; and, in all these situations, the defects above mentioned cease to exist, since in the first case the gorge is protected by the river, and in the others the faces and gorges are defended by the works or by the troops in the rear.

When it is required to defend any pass immediately on the right or left of redans, flanks, making salient angles with the faces at points near the extremities of the latter, are given to them, so that they then become what are also called bastions or lunettes; and the necessity of having a crossing fire for the defence of the ground in front, when the redans are not flanked by other works, has at times induced engineers to break the lines of parapet near the gorges, so as to form re-entering bends, and thus constitute a wing on each side at a right angle with the face.

Among the works constructed, in 1810, for the defence of Lisbon, redans were frequently placed on projecting knolls, in front of the great redouts, in order to flank the ground which was unseen from the latter: their gorges were protected by palisades, or by parapets, sufficiently slender to have been demolished by the artillery of the principal work, had the enemy succeeded in capturing them; and good communications, covered by the inequalities of the ground, or by earth purposely thrown up, were formed in order to allow the defenders, if necessary, to retire in security. The strong stone windmills, which in that country are often built on salient knolls of ground, were occasionally covered by redans of earth; and thus were formed good defensive posts, to each of which the mill served as a reduit or keep. During the struggle in the south of France, in 1813, Marshal Soult caused redans to be constructed as outworks, one below another, on the descending tongues of land which project from the main chains of heights whose summits he had crowned by strong redouts.

Two redans connected together, so as to leave one re-entering angle in front, form a queue d'hyronde; and the name of bonnet de prêtre has been sometimes applied to a work consisting of three redans so placed.

REDEMPTION. [Atonement.]

REDEMPTION, EQUITY OF. [Mortgage.]

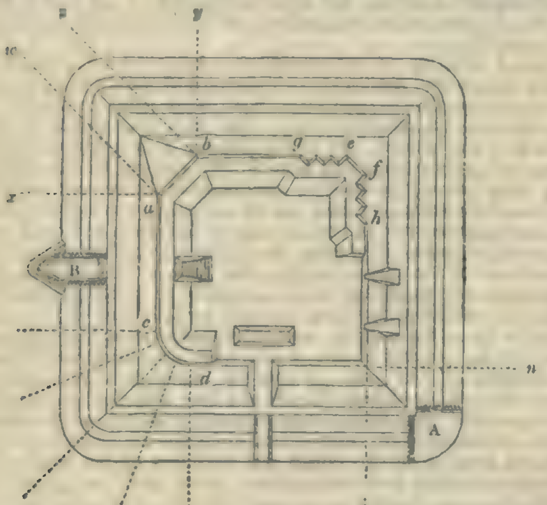
REDOUT is a general name for nearly every kind of work in the class of field fortifications; thus, a redan with flanks, a parapet enclosing a square or polygonal area, a work in the form of a star [Star-fort], and a fort with bastions at the angles, like the enciente of a fortress, are occasionally so called; but the second of these is the work to which the term is more particularly applied, and it is that which we propose now to describe.

When a work to be constructed on level ground is intended to contain troops and artillery for the purpose of preventing the enemy from occupying the spot, and when there is an equal probability that the work may be attacked on any side, that spot should be quite enclosed by the parapet; also if the defence is to continue only till succour can arrive from the army in the vicinity, flanking defences being then scarcely necessary, a quadrangular figure may suffice for the plan of the work, and there can be no reason why one side should be longer than another, or why the sides should form with each other any but right angles. But when the redout is to occupy an eminence whose figure on the plan is irregular, the faces of the work, whatever be the form thus produced, must necessarily be traced so as to correspond to the different directions assumed by the brow of the height; and if the fire of the work is intended to defend some fixed object, as a pass leading towards it, one of the faces must be perpendicular to the direction of that pass. It may be observed, however, that in general the number of faces, though not less than four, should be as few as possible. The ditches of all polygonal works without re-entering angles, are incapable of being defended by the fire from the parapets above, on account of the height and thickness of the latter, which prevent the soldiers from seeing them; and a curvilinear redout has, besides, two defects which are irremediable: the fires from its parapets are diverging, therefore they produce little effect while the enemy is advancing up to the work; and the ditch, on account of its form, is incapable of being defended from stockades within it. These objections apply with nearly equal force to redouts formed on regular polygons of more than five or six sides. The French, however, made a circular redout of casks for the purpose of strengthening the defence of the isthmus at St. Sebastian, previously to the siege of that place in 1813; and circular redouts of masonry are supposed to be useful on the sea-coasts. In the latter situation they are not liable to be attacked by infantry; and their artillery, which is mounted on traversing platforms, may be fired in any direction against ships or boats, should an enemy attempt a debarkation of troops. [Martello Towers.]

Every work in field as well as in permanent fortification is surrounded by a ditch, from whence is obtained the earth for the parapet, and by which the difficulty of carrying it by assault is increased. The ditch is generally crossed directly opposite the entrance by a bridge of timber, which should be capable of being drawn into the work, or replaced at pleasure. The entrance into a redout is at a re-entering angle, if there is one, otherwise it may be about the middle of one of the faces on the side which is least exposed to the view of the enemy; and, besides being barricaded, it is defended by the fire from a traverse, which is raised in the interior, and perpendicular to the direction of the passage.

Redouts for the defence of positions are in general intended to contain only about fifty men with three guns; but works in the form of irregular polygons have sometimes been constructed of a magnitude sufficient to contain 1600 men and twenty-five pieces of artillery; and such were the two principal redouts (on Mount Agraça and at Torres Vedras) formed in 1810, in order to protect Lisbon. These were expected to make a vigorous defence in the event of being attacked; but it is admitted that their *trace*, or ground-plan, was defective on account of the want of flanks, and perhaps they would have been prevented from falling only by the strong divisions of troops who were daily under arms in their vicinity. The redout constructed by the British in the neighbourhood of Toulon, in 1793, for the protection of the town and fleet, was a large work well furnished with artillery; yet, on being attacked by the republican troops, it was taken, after a gallant resistance, in which the enemy was twice repulsed. The ditches being undefended by flanks, the assailants, on being driven into them, re-formed their order with little molestation; and at the third attack they succeeded in getting possession of the work.

It is admitted among military men that in firing over a parapet, the soldier doing the duty as rapidly as possible, and fearing to expose himself while adjusting his musket, places the latter mechanically in a direction nearly perpendicular to the line of the face behind which he is stationed. It follows that in front of every salient angle of the work there must be an undefended sectoral space, as *m n* in the subjoined cut, which represents the plan of a square redout, in which space, in order to avoid the direct fire from the faces, the enemy may advance to the attack; and on this account it is recommended that the faces of the work should be disposed so that the angles may be turned towards ground which is impassable, or which will not permit the enemy to establish batteries for the purpose of enfilading those faces. When this disposition is not possible, various methods may be adopted by which the troops who man the work might direct some of their fire within those sectors. The simplest of these, and that which is generally put in practice, is to form the crest of the parapet near the angle, perpendicularly to the *capital* (the line bisecting the angle) as at *a b*; by which means the space between *w* and *z* may be directly defended, and the sectors *x w* and *z y* being small, very little attention on the part of the men about *a* and *b* will enable them to give their muskets an oblique direction so as to fire upon an enemy advancing within those spaces. A second method is that of rounding off the interior of the parapet at the angles, as at *c d*; but this has been objected to on account of the divergency of the lines of fire. The third method, which is much dwelt on by writers on fortification, consists in forming the interior of the parapet with indentations, as at *e g* and *f h*, alternately parallel and perpendicular to the capital, each indent being three feet long; and a parapet of this kind is said to be *en cremaillère.* It is evident that by placing men contiguously to the sides of these indentations, a fire may be kept up in either of the directions just mentioned; and by placing them at the angles, they may fire perpendicularly to the general face of the work. It must be observed, however, that the men cannot fire in these different directions at the same time, because, the muskets crossing one another, that of one man might be injured by the fire of the next, and therefore what is gained in one direction is lost in another. The only objections to this method are, that the parapet can be so formed only by men belonging to the corps of Royal Engineers, who are regularly trained to the construction of fortifications, but who may not be present when wanted; and that the unsteadiness of the soldiers in firing almost always renders such precision in the formation of the work useless.



The ditch of a redout having no flanks, being unseen and incapable of defence from the parapets, it has been proposed, in order to have some means of annoying the enemy when in the ditch, to form an enclosed space A, at one or more of the angles of the ditch, by planting a line of palisades across the latter on two contiguous faces of the work; the enclosure may have a roof of timber covered with earth, and loop-holes, three feet asunder, must be cut in the palisades, that the defenders may be enabled to fire along the ditches.

Another method, which may be advantageously adopted when a face of the work has considerable length, is to form, as at B, what is called a palisade caponnière, by planting across the ditch, at the middle of the face, two rows of palisades about eight feet asunder; each row being pierced with loop-holes. The entrance into the caponnière is by steps in the interior of the redout and a gallery under its parapet; and this work, as well as that at A, may have a roof, but in no case should such roof be above the level of the natural ground, in order that it may be concealed as long as possible from the view of the enemy. And if practicable, the floor of the caponnière may be sunk, so that the roof being only a few feet above the level of the ditch should not afford a bridge by which to enter the work. One of the redouts which was executed near Lisbon, being commanded by a height in its front, from whence the parapets might have been destroyed and the interior ploughed by shot, there was formed a gallery behind the counterscarp, and opposite one of the angles of the work, with loop-holes, from whence the ditch along each face might have been defended by musketry if the enemy had penetrated into it. The soil being chalk, no timber-frames were necessary for the support of the sides or top; and between this recess and the interior of the redout there was a gallery of communication passing under the bottom of the ditch.

A row of palisades is frequently planted quite along the ditch of a redout. Sometimes also the escarp of the work is fraized, or furnished with palisades planted in an inclined position, and a line of chevaux-de-frize is disposed upon the berme. In order to retard the advance of an enemy, the work is generally surrounded, at a distance not exceeding the range of musket-shot, by a single or double abatis, and often by two rows of pits called *trous de loup.*

The magnitude of a redout, whatever be its form, is determined by the strength of the garrison and the quantity of ordnance by which it is to be defended; all the men being supposed to be lodged within it. It was formerly the practice to allow on the area of the terreplein, within the foot of the banquette, ten square feet for each man, and 324 square feet for each piece of artillery; consequently when the redout is of a square form, the breadth of the banquette being known (about 11 feet), the length of the crest-line on each face could be easily determined. In order that the defenders may conveniently use their arms on the banquette, it has been customary to allow three feet along the crest of the parapet for each man, who is to stand contiguously to the interior slope; and it was once considered that a redout intended to make a considerable resistance when attacked on all sides, would be adequately garrisoned if the number of men in it were equal to the number of feet in the whole length of the crest of parapet; that is to say, if there were three ranks of men along each face, the work being supposed to be capable of containing such a number. It is said that each side of the square redouts which Marshal Saxe caused to be constructed at the siege of Maestricht, in 1748, was above 100 feet long, measured on the crest of the parapet, and that each redout was garrisoned by 500 men; and it will be found by computation that, consistently with the above rules, a square redout, each of whose faces is sixteen yards long, is the least that ought to be constructed; for if less, the interior within the banquette would not contain the number of men necessary to line its parapet with one rank. But the rule relating to the area within the banquette has been objected to as an unnecessary affectation of mathematical precision. The British engineers who constructed the works for the protection of Lisbon observe that, except at night, or at the moment of being attacked, part of the garrison will be on watch, or otherwise occupied outside of the work; and even at those times at least one-third will be under arms on the banquette. Colonel Sir John Jones states that the strengths of the garrison were finally determined by allowing two men per yard in the length of the parapet for the exterior works, and one man per yard for the interior works; deductions being made for the spaces where artillery was to stand. Each gun takes up about eighteen feet of the length of a parapet.

The crest of the parapet of a redout may be about 8 feet above the natural ground, unless the work is to be defiladed from some commanding ground in the neighbourhood, in which case it must be higher. The form of a section or profile of the parapet is similar to that which is used for permanent fortification [LINES OF INTRENCHMENT, *Fig.* 4], but the breadth of the superior slope may vary with the nature of the arm which the enemy can bring against it; three feet will suffice if the work can be attacked by infantry only, but it may be as much as 10 or 12 feet if it is to resist field artillery of the heaviest calibre. The superior surface of the parapet should slope down towards the exterior, so that the defenders may see the top of the counterscarp of the ditch in front; and when, from the great relief of the work, this is impossible, the counterscarp should be raised by earth obtained from the ditch to the height necessary for this purpose; taking care, however, to give the raised earth a gentle slope towards the exterior, that the enemy may not be screened by it. The exterior of the parapet and the escarp of the ditch are covered or revetted with sods when the earth has not sufficient tenacity to stand unsupported; and when the work is to resist the fire of heavy artillery, the revetment might consist of stout logs of timber planted obliquely in the ground or in the bottom of the ditch, and leaning against the face of the work. The interior of the parapet is usually revetted with sods or fascines.]

Redouts are intended to fortify military positions, for which purpose they usually occupy the heights and command the defiles; and their magnitude or number must depend upon the time afforded for their construction. [LINES OF INTRENCHMENT; MILITARY POSITIONS.] It sometimes happens that they are thrown up during the night to protect artillery on the wings, or in some important situation in front of the army, in expectation of an engagement taking place the next day; and then they are necessarily few and small. When

Marshal Soult was reduced to defensive operations in the south of France, in 1813 and 1814, he strongly entrenched the heights on all the frontier between the sea about Bayonne and St. Jean-de-Luz, and the mountains at St. Jean-Pied-de-Port; an extent of above sixteen miles. The works, which were executed in three months, were generally irregular polygons; and some of them were constructed for 500 men. More than a year was spent in raising the redouts which covered Lisbon; and consequently these were not only strong, but numerous beyond any other example. [Encampment.] They were of every trace, but mostly irregular polygons, whose sides sometimes formed re-entering angles, as the ground required: the two great redouts before mentioned were retrenched by interior parapets, which also served as traverses, and each salient point of the redout at Torres Vedras constituted an independent post.

Attack and Defence of a Redout.—In the attack of a small redout unprovided with artillery, light infantry, or riflemen, keeping for a time as much as possible covered by the inequalities of the ground, endeavour to surround the work, and, by a fire of musketry, directed towards the crest of the parapet, to diminish that of the defenders. The assailing troops then gradually close in upon the redout, and, while one division remains on the counterscarp to continue the fire, should the defenders show themselves upon the parapets, the rest descend into the ditch, where, having collected themselves in parties or small columns, they mount the parapet on each side of a salient angle: then developing themselves on the summit, they make a general discharge and enter the work. In order to avoid accidents in descending into the ditch, or in ascending the escarp, it is recommended that the bayonets should not be fixed by the assailants till they have gained the berme of the work.

But if the redout is of considerable magnitude, if it is furnished with artillery, and moreover protected by palisades in the ditches, and abatis or other obstacles in the front, the attack must be conducted with more powerful means. It should commence by a fire of artillery directed partly so as to enfilade the parapets, break down the palisades and derange the abatis, and partly to destroy the merlons which cover the artillery of the work. The fire of the latter being thus in some measure silenced, the light infantry, as in the former case, endeavour by musketry to prevent the defenders from manning the parapets; and in the mean time columns of troops advance towards the angles, being preceded by parties of sappers and miners, who make openings for them in the line of abatis, or cover with timbers the trous de loup, if such there be. If the ditch is deep, the descent into it, and the subsequent ascent of the escarp, must be facilitated either by placing scaling-ladders or by throwing in fascines or bags of hay; and any palisades or other obstacles which may not have been displaced by the artillery, must now be cleared away by the working parties which accompany the troops. The fire of the covering parties must cease while the assailants are mounting the parapet, but it must recommence if they should be repelled: in the latter case the storming troops reform their order in the ditch, and again attempt to enter the work. It may be supposed that at length they will succeed, when the defenders, if not provided with a redout, to which they may retire for the purpose of capitulating, must surrender at discretion. In 1793, the French camp under Valenciennes was protected by works which, though furnished with artillery, were open at the gorge; and in an attack, the British cavalry, having entered those works at their rear, made prisoners of all the defenders.

When a redout is threatened with an attack, the officer commanding it endeavours to provide against the event by disposing in front of the work all possible obstacles to the advance of the enemy, and by placing sand-bags on the parapets in order to cover the defenders, who are to fire through small intervals left for the purpose: these measures should be taken, if not before, during the night preceding the attack; since the latter generally takes place early in the morning. On the advance of the assailants, the artillery of the work is made to play upon their columns; and the fire of musketry commences as soon as the latter are within the proper range. These fires are kept up vigorously while the assailants are clearing away the obstacles, and until they have descended into the ditch. Should the work have flanks, and the guns behind them be not dismounted, a fire of grape-shot and of musketry must now be directed along the ditches; while hand-grenades and stones are thrown, and live shells are rolled into them from the parapets of the faces. The storming troops may however persevere, and may at length mount upon the parapet, in which case they must be received by a fire of musketry from the defenders on the terreplein; and the latter, if overpowered, must endeavour to retire or capitulate.

Any works constructed within others, in order to prolong their defence, or to afford a retreat for the troops who occupy them, are also called redouts; but by the French engineers, reduits or retrenchments. [Retrenchment; Block-house.]

REDU'CTIO AD ABSURDUM. [Absurdum, Reductio Ad.]

REDUCTION. This term is used in arithmetic in the well-known sense of the operation of turning one denomination of weights or measures into another: thus shillings may be reduced to pounds, or pounds to shillings. It is also used in the same sense throughout analysis, namely, that of bringing one form into another, making one question depend upon another, &c.; in fact, for transformation generally. It were to be wished that the latter word transformation should take its place whenever the two forms are of equal difficulty or the two questions of the same character, &c., and that reduction should be employed only when there is really a reduction; that is, a bringing down either of dimension or difficulty, &c. Many writers do use the word thus, and thus only, but others do not.

REDUCTION INTO POSSESSION. [Possession.]

REEFS, or CORAL REEFS, are a peculiar kind of rock which occurs abundantly in some parts of the ocean. They differ from other rocks in extending over a considerable space of the sea in length, with a very narrow width. Generally they are also only a few feet below water; so that on the side where they are washed by the open sea, a heavy surf is continually running against them.

Reefs appear under various forms. In some places they are contiguous to the shores, as in the Red Sea; in others they fringe the shores, being separated from them by a narrow channel of moderate depth. Sometimes they surround islands at a considerable distance from the shores, and the islands so encircled are almost without exception of volcanic origin. Very frequently they surround a portion of the sea, within which there are some small islands, which are often contiguous to the reefs, and seem to be a part of them, as both are composed of the same material. There are also coral reefs at a great distance from the land, which run nearly parallel to it, like a barrier. Among the latter are those of the Coral Sea, along the eastern coast of Australia.

The attention of navigators and naturalists was first attracted to those islands which go under the name of Lagoon Islands. A reef approaching in form to a circle surrounds a part of the sea and forms a lagoon, on the inner part of which there are usually several smaller islands, wooded and inhabited, which are contiguous to the reefs themselves, and frequently extend along them with little interruption. The water on the outside is always nearly unfathomable, but within the reefs good anchorage is generally found, and the reefs themselves have one or more openings of deep water by which the largest vessels may enter the lagoon. Accurate observers soon discovered that the reefs were composed of coral, and were the production of an animal. On these circumstances the first theory of reefs was founded. This theory received some addition from Forster, who accompanied Captain Cook on his second voyage. According to him, they are raised by these small animals perpendicularly like a wall, from a great depth to a very small distance from the surface of the sea. The waves afterwards bring sand, muscles, tang, and pieces of coral, and deposit them on the reef, which, in this way, is gradually raised above the sea-level, and becomes fit for vegetation. Currents and sea-fowls bring the seeds of marine plants, which, being decomposed, form a mould on which the cocoa-nut palm, when carried thither by the waves, thrives luxuriantly. This theory of Forster was adopted and extended by Flinders, who in surveying the coasts of Australia had abundant opportunities of observing the formation of these islands; and still more by Peron and Chamisso. The last-mentioned naturalist accompanied Kotzebue on his first voyage of discovery (1815-1818).

But facts have since been observed by Quoy and Gaimard, who accompanied Freycinet on his voyage, and published their observations in the 'Annales des Sciences Naturelles,' which are inconsistent with this theory. They found that the reefs did not entirely consist of coral, and that the layer of coral hardly exceeded a few fathoms in depth. Besides this the polypiaria which are able to form such a layer do not inhabit the sea to any great depth, and are not found where the water is more than 30 feet deep. They therefore supposed that these animals executed their work only in those parts of the sea where the bottom had been raised by some natural cause nearly to the surface of the water. They supported their theory by adducing the fact that the continuity of every lagoon-reef was broken at one or more places, so as to constitute a strait of very deep water, which could not be the case if these works were carried on at a depth of from 100 to 200 fathoms. This theory coincides with the views adopted by Von Buch, in his description of the Canary Islands, and has been adopted by Ehrenberg, in his pamphlet 'Ueber die Natur und Bildung der Coralleninseln und Corallenbänke im rothen Meere;' and by Darwin, in the third volume of the 'Surveying Voyages of the Adventure and Beagle.' The last-mentioned writer however does not doubt that the reefs which form the lagoon islands are composed of coral to a great depth, much greater indeed than those polypiaria which form them can live in. He explains this in a very ingenious way, by supposing that they formerly had an elevated island in the middle, but that in those portions of the sea where they now occur, the bottom of the waters was gradually lowered by subsidence, by which the polypiaria were enabled to continue their work farther, and the mountainous islands in the middle disappeared. In other parts of the Pacific and Indian oceans the contrary is supposed to have taken place: the bottom of the sea was elevated, and in these tracts volcanic islands occur. He observes that in this respect these seas may be divided into broad bands, in which an elevation and submersion has alternately taken place; and he draws from it some important inferences (p. 562-569).

Mr. Darwin has subsequently produced a work, entitled 'The Structure and Distribution of Coral-Reefs, being the first part of the Geology of the Voyage of the Beagle,' London, 1842, 8vo, pp. 214, in which he has stated his views in a systematic and comprehensive manner. He observes that, without any distinct intention to classify coral-reefs, most voyagers have spoken of them under the following heads, which are nearly identical with the descriptive terms already employed in this article:—Lagoon Islands, or Atolls; Barrier, or Encircling Reefs; and Fringing, or Shore Reefs. With respect to the lagoon islands, he remarks, everyone must be struck with astonishment when he first beholds one of these vast rings of coral-rock, often many leagues in diameter, here and there surmounted by a low verdant island with dazzling white shores, bathed on the outside by the foaming breakers of the ocean, and on the inside surrounding a calm expanse of water, which, from reflection, is of a bright but pale green colour. The naturalist, he adds, will feel this astonishment more deeply after having examined the soft and almost gelatinous bodies of the apparently insignificant creatures, the polypifers [POLYPIFERA, in NAT. HIST. DIV.], which construct these vast works; and when he knows that the solid reef increases only on the outer edge, which day and night is lashed by the breakers of an ocean never at rest. As the reef of a lagoon island generally supports many separate small islands, the word "island," applied to the whole, is often the cause of confusion; on which account Mr. Darwin in this work invariably uses the term "atoll," which is the name given to these circular groups of coral islets by their inhabitants in the Indian Ocean, and is synonymous with lagoon island. Reefs in most respects allied to those of the fringing class also occur around submerged banks of sediment and of worn-down rock; and others are scattered quite irregularly where the sea is very shallow. Mr. Darwin has given a separate chapter of his work to each of these classes of coral-reefs; but the classification, he states, admits of a more fundamental division into atoll-formed and barrier-reefs on the one hand, where there is a great apparent difficulty with respect to the foundation on which they must first have grown; and into fringing-reefs on the other, where, owing to the nature of the slope of the adjoining land, there is no such difficulty. Barrier-reefs, though little less marvellous in their structure than atolls, had previous to Mr. Darwin's researches received but little attention, and scarcely any attempt had been made to explain their origin. He concludes, in conformity with the summary statement of his theory, given above, that in them as well as in atolls, the foundation on which the coral was primarily attached has subsided, and that during this downward movement the reefs have grown upwards. "This conclusion," he says, "explains most satisfactorily the outline and general form of atolls and barrier-reefs, and likewise certain peculiarities in their structure. The distribution, also, of the different kinds of coral-reefs, and their position with relation to the areas of recent elevation, and to the points subject to volcanic eruptions, fully accord with this theory of their origin." After three descriptive chapters, Mr. Darwin describes in three others the distribution and growth of coral-reefs, gives in detail his theory of the formation of the different classes, and discusses their distribution with reference to the theory of their formation. In an appendix, every existing coral-reef is briefly described in geographical order, as far as the author possessed information; and their distribution over the equatorial regions of the globe is further illustrated by a map.

Still more recently, since the year 1847, the subject of coral-formations has been treated at great length by Dr. James D. Dana, in the 'Geology' of the 'United States Exploring Expedition,' during the years from 1838 to 1842, under Commander Wilkes, U.S.N. This volume was published at New York, but is undated.

REFINING. [ASSAYING; COPPER; LEAD; SUGAR.]

REFLECTING TELESCOPES. [TELESCOPE.]

REFLEXION AND REFRACTION. [LIGHT; OPTICS; REFRACTION, REFRANGIBILITY.]

REFORMATION is the name generally given to the great schism which took place in the Western Church in the first half of the 16th century, and by which a large part of the population of Europe has become separated from the Church of Rome; besides which, the great majority of the people of the United States of North America, as well as of the English and Dutch colonies, follow the same mode of faith.

In order to understand correctly the history of the Reformation, it is necessary to be acquainted with the social, political, and intellectual state of Europe in the 15th century; and for this purpose the histories of the councils of Constance and of Basel, and the 'Historia Bohemica,' by Æneas Sylvius Piccolomini, are of great service. [PIUS II., in BIOG. DIV.] Previous to the Reformation the see of Rome claimed of divine right, and asserted, with the assistance of the lay power of the various states of Europe, an absolute authority over the whole Christian Church; indeed, a universal authority, as exemplified by the gifts of the Western world, the inhabitants being heathens, to the monarchs of Spain and Portugal; while the Greek Church was denounced as heretical. By virtue of this supreme authority, the Roman pontiff decided absolutely all doubts and disputes which might arise, whether in matters of doctrine, jurisdiction, or discipline: his decisions were considered as infallible; and whoever resisted or gainsayed them was considered a heretic, and as such liable to canonical censures, and also to the temporal penalties awarded by the canon law against heretics. The government of the Church was therefore absolute; and the Church, or rather the bishop of Rome, as head of the Church, assumed also a supremacy even in temporal matters, although the exercise of this last supremacy was resisted by various princes. [GREGORY VII.; INNOCENT III.; INNOCENT IV.; GREGORY IX., in BIOG. DIV.]

The great object of the Reformers of the 16th century was to overthrow the principle of absolutism in the government of the Church, by contesting the infallibility and supremacy of the bishop of Rome. This had been already contested, and indeed set aside by the councils of Constance and of Basel; but the point of contention had never been finally and permanently settled. The Reformers of the 16th century, however, went much farther: they denied the absolute authority even of the councils, and they leaned towards the popular or democratic principle in religious matters, by allowing the right of individual interpretation of the Scriptures, and discarding all tradition and human authority in matters of faith; and as in the course of their struggle they were met by several dogmas or doctrinal tenets derived either from passages of the Scriptures as interpreted by the Roman Church, or from tradition, or from decisions of the councils or decretals of the popes, which were urged in opposition to them, they set about translating and commenting on the Scriptures, substituting a different interpretation of the disputed passages, and thus sapping the very foundations of the whole fabric of Church authority.

It has been maintained by several writers that the principles asserted by Luther and other reformers were those of the early ages of the Church; but all that can be proved seems to be that in almost every age since the apostolic times there has been here and there a display of opposition to the absolute system in the Church; that some peculiar doctrines of Luther and Calvin had been asserted by others long before them; and that the Valdenses especially, and their neighbours of the valleys of Dauphiné, had retained from time immemorial a system of Church discipline similar to that established by the Reformation in the churches of Switzerland and Scotland.

The progress of the Reformation in Germany and Switzerland has been related in the BIOG. DIV. under the names of the chief actors in that great movement. [LUTHER; BUCER; MELANCTHON; ZWINGLI; CALVIN; CHARLES V.; FERDINAND I.; MAURICE, Duke of Saxony; and others.]

The Reformation in England sprung from among the people and the clergy. It had begun with Wycliffe; it spread from England to Germany among the Lollards and the Hussites, and was carried back from the Continent to the shores of Britain with a fresh impulse from the preaching of Luther, Bucer, and the Swiss reformers. The schism of Henry VIII. paved the way, but it did not originate, nor promote, nor establish the doctrines of the Reformation; they made their way rather in spite of, than by the favour of, that capricious king. It was only under his successor, Edward VI., that the Reformation became established by authority. Still the origin of the Church of England as a body independent of Rome dates from the wayward deeds of Henry VIII., and when that Church afterwards adopted the reformed doctrines, there was a great admixture of political and state reasons in the final establishment of it, especially under Elizabeth, and consequently much severity and harshness were exhibited towards those who adhered to the old religion, which threw for a time a dubious light over the ascendancy of the Reformation in England.

For its progress and final settlement, we must refer to the histories of this country, and the articles BUCER; CRANMER; CROMWELL, THOMAS; EDWARD VI.; ELIZABETH of England; GARDINER; HENRY VIII.; MARY I. of England; and POLE, REGINALD, in BIOG. DIV. For the Reformation in Scotland, see KNOX and MARY STUART, in BIOG. DIV.

In France, as early as 1530, the doctrines of the Reformation had found their way from Germany and Switzerland. Some of those doctrines had lingered in the south for ages before, especially in the mountains of Dauphiné bordering on the Valdenses. Pierre Robert d'Olivet, Michel Cop, rector of the University of Paris, Beza, and others, adopted and spread them; and Margaret, sister of Francis I., and Renée, daughter of Louis XII., gave them their countenance. But Francis I., who through policy secretly encouraged the Protestant states of Germany against the emperor, persecuted his own subjects who had embraced the new doctrines. The stake and the faggot were employed at the same time in France and in England, by Francis and Henry VIII., against the Reformers. In 1535, Francis, attended by his family, the clergy, the magistrates, and other officers of state, was present at the burning by a slow fire of six citizens of Paris, who had been condemned by the parliament as heretics. The execution lasted two hours. This was the forerunner of many scenes of a similar character which disgraced France for more than half a century. The persecutions, the civil and religious wars, the truces and other vicissitudes of the French Calvinists, during the reigns of Francis I., Henri II., Francis II., Charles IX., and Henri III., are part of the history of France. De Thou, in his 'Historiæ sui Temporis,' Beza, 'History of the Reformed Churches of France,' and the 'Mémoires et Correspondence de Duplessis Mornay pour servir à l'Histoire de la Reformation et des Guerres civiles et religieuses en France depuis l'an 1571 jusqu'en 1623,' Paris, 1824–34, are the best contemporary authorities for that period. At last, Henri VI., by his 'Edit de Nantes,' 1598, acknowledged the Reformed communion as the lawful creed of a part of the French population.

The doctrines of the Reformation had made many converts in the Netherlands in Luther's lifetime, and a fresh influx of Calvinists from France and Switzerland increased the number of dissidents from the Roman Church. The wild outbreak of the Anabaptists at Leyden, Münster, and other places, threw discredit for a time on the cause of the Reformation; but these disturbances were soon put down. During the reign of Charles V., the friends of the new doctrines in the Netherlands were persecuted as heretics, and many suffered death by sentence of the regular courts of the country; but after Charles abdicated, at Brussels in 1555, in favour of his son Philip, the latter, in order to extirpate heresy more effectually, sent inquisitors from Spain to establish the tribunal of the Holy Office in the Netherlands. This gave rise to a strong opposition both from the nobles and the people, which, being mixed up with political grievances, led to an open insurrection against Philip. During the long war which followed between the rebels and the Spanish forces, some of the provinces separated from the rest, and the seven northern provinces of Holland, Zealand, Guelderland, Friesland, Utrecht, Overyssel, and Groningen formed a confederacy by the name of the "Seven United Provinces," and proclaimed liberty of conscience. The great majority, however, of the population of the seven provinces followed the doctrines of Calvinism, and have remained attached to them ever since. The confession of faith for the provinces of the Netherlands was published in 1562, and was afterwards approved by the members of the synod of Emden in 1571. The disputes that broke out afterwards between the Arminians and Gomarists are related in the article ARMINIUS, in BIOG. DIV. The synod of Dort, in 1618, revised and republished the Netherlandish confession.

About the year 1556 the Lutheran or Protestant creed was adopted as the state religion in the kingdoms of Denmark and Norway, under King Christian III. Denmark, however, as well as Sweden, has retained episcopacy.

The Protestants or Lutherans, as well as the Calvinists, became very numerous in Poland under the reign of Sigismund Augustus, and many of the high nobility had embraced the Reformed doctrines. An approximation was effected between the Lutherans and Calvinists, and a confession was drawn up, in concert, by the clergy of both communions, at Sandomir, in 1570, called "Consensus Sandomiriensis." The followers of the Reformation, however, never constituted the majority in Poland, and being afterwards persecuted under Sigismund III. and some of his successors, their number was greatly reduced; but they were never annihilated, and Lutheran and Calvinist congregations have continued to exist in most towns in Poland. The most complete account of the Reformation in Poland is in the 'Historical Sketch of the Rise, Progress, and Decline of the Reformation in Poland,' 1838, by Count Krasinski.

In Hungary and Transylvania both Lutherans and Calvinists were established early, and they constitute a considerable proportion of the population of those countries. The recent attempt of the Emperor of Austria to repress them and to abolish their privileges, has led to discontents, aggravated also by other infringements on the constitutional rights of the people, of which the results are yet (1861) uncertain.

The doctrines of the Reformation spread into Italy from Switzerland and Germany at an early period, and found proselytes in several towns, especially Ferrara, where Renée of France, duchess of Este, countenanced them; at Lucca, Faenza, Milan, and Naples. Several learned monks and priests,—the Capuchin Ochino of Siena; Vermigli, a canon of Florence; Montalcino, a Franciscan friar; Lorenzo Romano, an Augustine monk, and others,—adopted and preached the new tenets. Meetings and private places of worship were established in various towns. Paul III., alarmed at this change, established, in 1543, the Congregation of the Holy Office at Rome, with full powers to proceed against heretics independent of the ordinaries; and he also sent inquisitorial commissioners into the various provinces of Italy for the same purpose. By these means he effectually checked the course of the Reformation, and his successors Paul IV. and Pius V. completed its extirpation by the most severe measures. Many of the followers of the Reformed doctrines suffered death either by fire or by the sword of the executioner. [PIUS V., in BIOG. DIV.] Numerous families emigrated to Switzerland on account of religion, especially from Tuscany and Lombardy. A considerable district of Calabria, near Cosenza, which is said to have been originally peopled by a colony from the valleys of Piedmont, having publicly adopted the tenets of the Reformation, and sent for some Calvinist preachers from Geneva to teach them and their neighbours, the Duke of Alcala, Spanish viceroy of Naples, about 1560, sent several inquisitors with a body of armed men, who arrested and put to death many people in the village of San Sisto. Upon this the neighbouring villages broke out into open revolt. The town of La Guardia Lombarda sustained a regular siege. Being taken at last, a general massacre of the inhabitants took place, with circumstances of the greatest atrocity. (Botta, 'Storia d'Italia,' b. x.)

In Spain, the doctrines of Luther and Calvin spread in the 16th century, and made numerous proselytes at Seville and other places; but the arm of the Inquisition effectually eradicated them. M'Crie has written the history of the rise, progress, and extinction of the Reformation both in Spain and in Italy.

Among those authors who have written or commented upon the history of the Reformation, the following deserve notice:—Among the Protestants—Sleidan, *De Statu Religionis et Reipublicæ, Carolo quinto Cæsare Commentarii*, first published in 1555, and translated into English by E. Bohun, with a continuation to the end of the Council of Trent in 1562, and published in 1589; Spalatinus, *Annales Reformationis;* Beausobre, *Histoire de la Reformation;* Burnet, *History of the Reformation;* Seckendorf, *Commentarius Historico-Apologeticus de Lutheranismo;* Loscherus, *Acta et Documenta Reformationis:* and among the Roman Catholics — Maimbourg, *Histoire du Lutheranisme;* Pallavicini, *Historia Concilii Tridentini;* Bossuet, *Histoire des Variations des Eglises Protestantes;* besides the general historians of the Church.

REFORMATORIES. By the Acts 17 & 18 Vict. cc. 86 and 169, and 20 & 21 Vict. cc. 48 and 109, various provisions are made by which magistrates may send juvenile offenders to reformatories, instead of to prison, there to be detained for certain periods, at the discretion of the magistrate before whom the young delinquent is charged. The reformatories must be inspected and certified by a government inspector before they are legally entitled to receive juvenile offenders under the Acts referred to. Parents who have sufficient means are bound to pay a certain amount towards the expense of maintaining their children while detained in reformatories. Several reformatories for adult criminals, both male and female, are likewise in operation. In 1856 an institution called the Reformatory and Refuge Union was established in London, for the purpose of promoting the extension of reformatory operations. From a statement published by this Union, it appears that there were at the commencement of 1860, in England and Wales, 57 reformatories, with accommodation for about 4500 inmates; in Scotland 17, with accommodation for 1840 inmates; and in Ireland 6, with accommodation for 680 inmates. The accommodation indicated by these figures does not show the actual number of inmates at the time referred to, as many of the houses were only partially occupied.

The reformatory best known, and on the largest scale in this country, is that of the Philanthropic Society at Red Hill, near Reigate, Surrey. The founder of the Philanthropic Society, Robert Young, commenced his efforts on behalf of the children of criminals in 1788. He took in succession four small houses at Hackney for their reception, and placed in each a mechanic or artisan to instruct them in useful labour. The society was incorporated in 1806, and increased in importance and in usefulness. For the last eleven years its extensive operations have been carried on at Red Hill, where the society's farm occupies an area of about 240 acres. By the Act of Incorporation, the objects of the society are defined to be the children of convicted felons, or children who have themselves been guilty of criminal practices; and of late years admissions have been principally of the last class, especially juvenile offenders sentenced to detention under the Act 17 and 18 Vict. c. 86, and 19 & 20 Vict. c. 109. To be eligible for admission, the boy must be under fifteen years of age, of sound bodily health, and capable of receiving mental instruction and industrial training. By special arrangement, this institution receives juvenile offenders from the eastern division of the county of Sussex, from the counties of Surrey, Somerset, Notts, Salop, Lincoln, Montgomery, and Oxford; from the Isle of Ely; from the boroughs of Nottingham, Hastings, Brighton, and Reading; and from the city of London. In consideration of the voluntary subscriptions received from the public, a limited number of boys are received into the establishment free of charge. The number of boys under the society's care at one time is usually about 260; they are divided into five sections or "families," each with a separate house, and a master or "father." This plan was adopted from the system so admirably carried out at Mettray by M. Demetz, although, the families at Red Hill being larger in number than those at Mettray, the control of the master is not so effective. The separation of the families, however, is so well kept up that, except at chapel, many of the boys never see each other. The boys learn and work alternately, half of the number being at school while the other half are employed as shoemakers, as tailors, as assistants in the dairy, in brickmaking, or at farm-work. Each school has a playground attached. There is also a bathing-pool, which, under proper regulations, is frequently used. The boys generally enjoy good health. The establishment is made to produce as much for its own support as possible: thus all the shoes, clothes, &c., required for the boys are made in their own workshops; grain, potatoes, and garden-stuffs are raised on the farm; the dairy supplies the milk and butter required, and is in such repute that the surplus produce is in great demand in the neighbourhood. Bread is made on the establishment. It is pleasing to visitors to observe the excellent feeling which prevails between the boys and the masters and the officers of the institution. The conduct of the boys at chapel is exceedingly decorous: in giving the responses, and in accompanying with their voices the neat little organ placed in the chapel, they manifest a gratifying amount of earnestness. Forty-five of the boys were confirmed by the Bishop of Winchester in May, 1859. The disposition of the boys may to some extent be judged of from the circumstance that, of 159 boys who were out on leave during 1859, only 4 did not return to time. Nineteen deserted the school during the year. Five had to be committed to prison.

Among the sources of income of the Philanthropic Society, the following may be noticed:—The profit of the farm-work in 1859 was 448*l.*; on brick-making, 106*l.* The amount of work done by the boys for employers in the neighbourhood was 156*l.*; while upwards of 6000*l.* was received from government under the Reformatory Acts. The outlay for training and maintenance was, on an average, about 20 guineas for each boy; the total expenditure was 7200*l.*

The number of boys received during 1859 was 99; of these about half had lost father or mother, or both; many were the children of drunken and immoral parents. Of those discharged during the year, 43 emigrated, 6 were apprenticed, 5 sent to service, 4 to sea, and 35 were sent to friends. About 900 boys have been sent out as emigrants to Canada, the United States, and Australia, since the commencement of the school. From a statement showing the disposal of the boys during four years, 1855-1858, it would appear that about 11 per cent of the emigrants, and about 28 per cent. of those in home employments, relapsed into crime.

Much of the success of the Philanthropic Society's operations is due to the excellent management of the Rev. Sydney Turner, now government inspector of reformatories, who was chaplain and secretary to the institution for a number of years.

The following reformatories are in operation in and near *Bristol*:—Kingswood (established 1852), for 100 males; Red Lodge (1854), for 60 girls; Arno's Court (Roman Catholic, 1856), for 300 females. The *Liverpool* Farm School, situated at Newton, near Warrington, with accommodation for 80 boys, was established in 1859. The magistrates in Liverpool have taken pains to apply the provisions of "The Youthful Offenders Acts," and the results have been highly satisfactory. In the five years preceding the passing of these Acts the average number of juvenile offenders committed to prison was 1030; in the five years following the average fell to 751; the highest number was 1148 in 1852; the lowest 486 in 1858. The daily average of juveniles in prison in 1854 was 110; in 1859 it was a fraction under 25. The gangs of juvenile offenders which formerly infested and plundered the town have been quite broken up. Parents have been called upon, in accordance with the provisions of the Acts, to pay towards the expense of thus reforming and training the children they have neglected, the amount reaching, on an average, about 250*l.* a year. *Exeter* had a Female Refuge for discharged prisoners of the Western Counties as early as 1836, with accommodation for 20 inmates: it has now, in addition, the Devon and Exeter Reformatory Farm School, at Brampford Wood, founded in 1855, for 30 boys, and the girls' reformatory for the Western Counties, for 50 inmates, commenced in 1858. The Castle Howard Reformatory, at Welburn, near *York* commenced in 1856, with accommodation for 80 boys, receives youths sentenced to detention who have been previously once, or oftener, convicted, from the North and East Ridings, the City of York, and the town of Hull. The boys are employed chiefly in spade husbandry, and are much in request as labourers by the farmers in the neighbourhood. The number of juvenile offenders in the North and East Ridings has greatly diminished since the opening of the school. With respect to the town of Hull, the testimony of the stipendiary magistrates is, that "juvenile crime, as a system, is broken up." The *Manchester* and *Salford* Reformatory, at Blackley, has accommodation for 50 boys. At *Birmingham*, the Saltley Reformatory Institution, Small Heath, has accommodation for 100 boys; and the Smethwick Reformatory has accommodation for 45 girls. At *Wakefield*, the West Riding Reformatory School for girls was commenced in 1856.

REFRACTION, REFRANGIBILITY. Refraction is the turning of a ray of light, heat, or other imponderable substance from its direction, when it falls obliquely on the surface of a medium differing in density from that through which it had previously moved. The differently coloured rays of light have different degrees of refrangibility, as evidenced by the common prismatic spectrum; in other words, the refractive indices of different lights vary for a given medium. The fundamental law of refraction and the optical effects of this law are discussed under the heads Light and Optics, and a table of refractive indices is given in the article Optics, Practical. For the different refrangibilities of the rays, the articles Dispersion and Achromatic may be consulted, and for one of the most striking phenomena thence arising see Rainbow. On the subjects of Fraunhofer's lines and of double refraction, see Dispersion and Undulatory Theory.

The doctrine of refraction, as distinguished from reflection, is called dioptrics, and the caustics formed by the continued intersections of refracted rays emanating from a luminous point, are termed diacaustics; properly speaking, these are surfaces, but by confining the investigation to the plane of refraction, they are generally treated as curves. A diacaustic curve, like a catacaustic, has the property of being rectifiable. They are noticed in the articles above quoted, but they are rather objects of analytical dexterity than of practical use.

So long as the medium into which the refracted ray enters remains of uniform density, the ray will pursue a straight course, but every alteration of density in the medium gives rise to a corresponding deviation in the path of the ray. Now the air is a medium of which the density continually increases as its altitude above the surface of the earth diminishes; its density is also altered in the same stratum by inequality of temperature, and frequently from the aqueous and other vapours which it holds. Hence arise the ordinary terrestrial refraction and the phenomena of Mirage, Fata Morgana, &c., which are treated under their respective heads.

A ray of light proceeding from a star which is not vertical, on entering the atmosphere is bent towards the radius drawn from the earth's centre to its point of incidence, and upon its successive incidences on the lower strata it continues to bend towards the successive radii, thus describing a curvilinear trajectory through the air. The star is visible in the direction of the tangent to this curve, at the point at which it meets the eye of the spectator; hence the apparent altitude of the stars is increased by refraction, and thus the sun, moon, &c., are visible before the real time of rising and after that of setting.

From the causes above assigned for atmospheric refraction, it follows that the nearer the direction of the ray is to the plane of the horizon, the greater is its refraction, and the refraction is nothing when the ray is vertical. This is the cause of the apparently oval forms of the sun and moon in the horizon; for the sun's angular diameter being taken at 32 minutes, its lower limb is elevated through horizontal refraction more than its upper by 4 minutes 54 seconds.

Atmospheric refraction of the solar rays after sunset, combined with subsequent reflection, is the cause of twilight, and also of the light thrown on the moon's surface when eclipsed by the earth.

The amount of refraction of rays proceeding from a celestial body would be proportional to the tangent of its zenith distance, if the atmosphere were homogeneous, and the zenith distance sufficiently small to allow us to regard the refracting strata of air as bounded by parallel surfaces. Not only, however, is the atmosphere defective in homogeneity, but its state is continually altering, as shown by the barometer, thermometer, and hygrometer. A partly empiric formula, the result of numerous observations made by Bradley, gives a good correction relative to the first two of these instruments, namely:—

Let $r = 57'' \times$ tang. zenith dist. (z);
h = height of thermometer (Fahrenheit);
a = altitude of barometer in inches.
R = the required refraction; then shall

$$R = 57''. \frac{a}{29{,}6} \cdot \frac{400}{350+h} \cdot \tan(z - 3r) \text{ nearly.}$$

Similar formulæ have been the objects of analytical research to Laplace and other modern mathematicians; their results are however not well adapted for insertion in this work.

REFRACTION, DOUBLE. [Polarization of Light.]

REFRIGERANTS are remedial agents which directly diminish the force of the circulation, and reduce the heat of the body or a portion of it, without occasioning any diminution of the ordinary sensibility or nervous energy. This definition must not be considered as excluding *cold* from among the number of such agents, because it is capable, when carried to extremes, of rendering the sensibility null, and utterly extinguishing the nervous power; it is only its moderate and therapeutical employment which is here contemplated. Cold, however, has of late been recommended to be carried locally to an extreme degree, utterly destroying for a time and special purpose the sensibility, thus acting as an anæsthetic. It is likewise applied to the spine with much benefit in some cases of tetanus.

The manner in which refrigerants effect the ends which they accomplish is far from being understood; and a remarkable feature in their character is, that they display their peculiar effects chiefly when the action of the organs is above their natural standard, and more heat than natural is evolved. Till we have a perfect knowledge of the sources and mode of formation of animal heat, we are not likely to possess a correct theory of their mode of operating; and at present, whatever plausibility the mere chemical hypothesis of Dr. Murray exhibits, we cannot consider the evolution of animal heat to be other than a vital process. This function is mainly carried on in the capillaries or extreme vessels, and is much influenced by the amount of supply of nervous energy to these vessels. Hence, when a limb is paralysed, it is colder than the opposite sound member; or when a single nerve is injured, the parts supplied by it have a lower temperature than the surrounding ones. Whatever, therefore, hinders the free communication of the nervous power to a part or to the whole system, will lessen its quantum of animal heat. By applying to the surface of the body any acid, the calibre of the capillaries is lessened, and hence the paleness which is observed, owing to less blood entering them. As the blood furnishes the pabulum from which the nerves evolve the heat, the less fuel the vessels contain, the less potent will be the heat resulting. The introduction of any article of the class of refrigerants into the stomach appears to operate by sympathy on the whole vascular system, as may be seen in the case of dilute sulphuric acid checking hæmorrhage. The agents which are usually regarded as refrigerants are weak vegetable acids, or very greatly diluted mineral acids; some saline, neutral, or super salts; and cool air, ice-cold water, and externally evaporating lotions. An indirect refrigerant is found in diminishing the quantity of animal food. [Antiphlogistic Treatment; Bathing; Lotions.]

REFRIGERATION OF THE GLOBE. Since the mathematical researches of Fourier regarding the diffusion and conduction of heat in a mass constituted as the earth appears to be in the parts near the surface, have become in some degree known, geologists have been much encouraged in attempting to connect with a gradual change and diminution of the internal temperature of the globe, such as would be consistent with Fourier's theoretical results, the higher order of geological inferences. The phenomena of a general if not universal base of once melted rocks below all the strata, the peculiar (often called metamorphic) condition of the lowest of these as compared with the upper, the absence or rarity of fossils in the lowest strata, the evidence of even general high surface temperatures on the ancient land and in the ancient sea as contrasted with the modern distribution of climates, are all consequences supposed to be derivable from the assumption of the earth having once been thoroughly very hot, and being now partially cooled by radiation of heat into the cold planetary and stellar spaces around us. But though such a deduction of phenomena from a primal condition of our planet is or appears to be correct enough to justify geologists in employing the hypothesis as a means of discovering truth, they must be careful neither to disregard inquiries into the certainty of the fundamental assumption, nor to neglect a scrupulous examination of its consequences.

On the first point Professor Whewell communicated to the Geological Section of the British Association at Dublin (1835), some observations which are likely to be influential on the second point, and which can neither be condensed nor amended.

"The heat of the interior parts of the earth has always been treated of by those who have established the theory of heat upon mathematical principles. They have hitherto considered it as proved upon such principles, that the increase of temperature of the substance of the earth as we descend proves the reality of an *original heat*. But M. Poisson, in his 'Théorie de la Chaleur,' just published, dissents from this opinion, and is disposed to assign another reason for the higher temperature below the surface. He observes that the cosmical regions in which the solar system moves have a proper temperature of their own; that this temperature may be different in different parts of the universe; and that, if this be so, the earth would be some time in acquiring the temperature of the part of space in which it has arrived. This temperature will be propagated generally from the surface to the interior parts. And hence, if the solar system moves out of a hotter into a colder region of space, the part of the earth below the surface will exhibit traces of that higher temperature which it had before acquired. And this would by no means imply that the increase of temperature goes on all the way to the centre." ('Report of the British Association for 1835,' p. 66.)

A speculation, perhaps in reality involving such views as those of M. Poisson, though founded on examinations and inferences among the Helvetic Alps, was subsequently brought prominently before the geological world by M. Agassiz. According to this very distinguished naturalist, there is evidence from the peculiar effects left by glaciers, in the valleys of Switzerland and on the surface of the Jura Mountains, that the icy mantle which now wraps the High Alps once filled the valleys for miles beyond its present limits, and, consequently, that the blocks of Mont Blanc and the Valorsine were carried across the Lake of Geneva to the Jura, by a mere glacier movement across an ice-filled hollow. Dr. Buckland and Mr. Lyell have endeavoured by similar evidence and reasoning, by the evidence of scratched, smoothed and grooved surfaces of rock, and the appearance of moraine heaps in the Highlands of Scotland, near Edinburgh, and in Cumberland and Westmoreland, to prove that glaciers anciently covered large tracts of the Caledonian and Cumbrian regions. ('Geol. Proceedings,' 1840, November and December.)

Moreover, it is understood to be the opinion of M. Agassiz that the icy covering thus attempted to be demonstrated by its remaining effects in the mountainous parts of Great Britain, "once extended over all the north of Europe and the north of Asia and America," and that in this "mass of ice the elephants and other mammalia found in the frozen mud and gravel of the arctic regions were imbedded at the time of their destruction." To the quick melting of this immense mass of ice and the currents of water which resulted, the author attributes the transport and deposition of the "masses of irregularly rounded boulders and gravel which fill the bottom of the valleys, innumerable boulders having at the same time been transported, together with mud and gravel, upon the masses of the glaciers then set afloat" (See the work of M. Agassiz, entitled 'Etudes sur les Glaciers de la Suisse,' and the accounts of his observations before the British Association at Glasgow in 1840.)

Now it is obvious that in examining this speculation, two ways are open: first, a careful comparison of the phenomena with the hypothesis which is proposed for their explanation; secondly, an inquiry into the probability of the conditions which might render such a general and extreme refrigeration of the globe as the hypothesis requires *possible*. Confining our remarks to the former process, we may observe: first, that to admit the ancient existence of glaciers in some of the Highlands and Cumberland valleys which display *glacial effects*, is one thing; to admit *glacial action* as the physical cause of the dispersion of boulders and gravel, another. Glaciers are found at this day in corresponding latitudes and at corresponding elevations in the southern parts of America: a local effect of causes which may be conceived to have formerly produced an equal effect in the northern zone: but the distribution of the boulders and gravel is so peculiar and yet so various, the dispersion of them so wide in regions where, according to the present configuration of the land, they could not be pushed by glaciers, nor carried by floating ice; and the connection of these circumstances with a great change of organic life, so strict, that it is hardly conceivable such effects could be due to anything but a cause simultaneously general or successively repeated. Of the physical causes by which the explanation of this great phenomenon has been attempted, it will suffice to mention three:—

1. Great and extensive oceanic action consequent on mighty misplacements of the solid land, and corresponding changes of land and sea.

2. Repeated local displacements of land and sea, and consequent litoral action.

3. The melting of great circumpolar glaciers, and the drifting of floating ice.

During the period of nearly twenty years which has elapsed since the first publication of the preceding portion of this article, much has been done on the subject, both by mathematicians and geologists. The consequences of admitting the hypothesis of the refrigeration of the globe, and the history of the gravel containing sea-shells alluded to above, and now called the "northern drift," have been rigorously investigated. Until within this period, the only change of climate which had been recognised by geologists as having taken place during the earth's geological history was one from a higher to a lower temperature; and for those who believed in the primitive heat of the globe, however originated, that heat afforded one obvious cause for this higher temperature at remote geological epochs. When, however, an examination of the phenomena of the "glacial epoch" (first conceived by Agassiz) during and on the gradual termination of which that drift was accumulated, rendered it necessary to recognise a change of climate in our own region of the globe (as indicated by the facts noticed in the proposition 1 above) from a lower temperature during that period to a higher subsequent temperature, new conditions were added to the problem. As we have seen, two other causes had been already suggested, which might possibly account not only for a change from a higher to a lower superficial temperature, but also for oscillatory changes. One of these assigned causes rested on the fact of the translatory motion of the whole solar system in space, and the hypothesis proposed by Poisson of the variable temperature of the different regions through which it might pass; thus the other cause assigned, pointed to in propositions 1 and 2 above, was the influence of different configurations of land and sea on the climatal state of particular portions of the earth's surface. No attempt, however, was made to examine the efficiency of these different causes to account for all the phenomena which might be referable to them, until Mr. William Hopkins, F.R.S., of St. Peter's College, Cambridge, when president of the Geological Society of London, undertook a remarkable investigation contained in a paper communicated to that society in 1851, and published in its 'Quarterly Journal,' vol. viii., pp. 56—92, 'On the Causes which may have produced Changes in the Earth's Superficial Temperature.' He also returned to the subject in his anniversary address to the society in the following year, printed in the same volume. From these papers is derived the following view of what may be regarded as the actual condition of the theory of the refrigeration of the globe; but we have stated the subject in a somewhat different order from that adopted by the author.

If there be any propositions in experimental science which may be deemed incontrovertible, the following, Mr. Hopkins conceives, is one of them:—"If a mass of matter—such, for instance, as the earth with its water and its atmosphere—be placed in space of which the temperature is lower than its own, it will necessarily lose a portion of its heat by radiation, until its temperature ultimately approximates to that of the circumambient space, unless this reduction of temperature be prevented by the continued generation of heat." This proposition, it will be seen, is equivalent to an explicit statement of the theory of the refrigeration of the globe in all its generality. Now, assuming the primitive temperature of the globe to have been very much greater than at present, there is manifestly no difficulty in accounting for any higher superficial temperature than the present, at past epochs, provided those epochs be sufficiently remote. They must, however, be exceedingly remote to enable us thus to account for a variation of temperature which should sensibly affect the climatal conditions in any part of the earth. If the cooling of the earth were to continue for an indefinite period of time,—assuming the temperature of external space, the sun, and the earth's atmosphere to remain as at present,—the superficial temperature would approximate indefinitely near to a certain limit. The difference between that limit and the earth's present superficial temperature is the effect due to the remains of the primitive heat. Theory gives us a simple relation between the amount of this effect and the rate of increase of temperature in descending beneath the earth's surface. Knowing the one, we can immediately determine the other, and thus, having ascertained the rate of increase, we know the amount of superficial temperature which is now due to the earth's primeval heat, assuming always that heat to be the cause of the existing internal temperature of the globe. This amount is thus proved not to exceed about the one-thirtieth part of a degree of the Centigrade thermometer, so nearly has the earth's superficial temperature approximated to that ultimate limit beyond which it could never descend, supposing external conditions to remain the same. It has been shown, on high mathematical authority, that to reduce the superficial temperature of the earth by one-half of the above amount, or one-sixtieth of a centesimal degree, it would require the enormous period of *one hundred thousand millions of years*. "It would doubtless," says Mr. Hopkins, "require us to go back into the past some such immense period as this to arrive at the epoch when the superficial temperature should have exceeded its present amount by even one or two degrees. At the same time, the rate of increase of temperature in descending beneath the surface would be much more rapid than at present. [The present rate is about 1 Fahr., or $\frac{5}{9}$° C. for every 60 feet of depth.] If the superficial temperature amounted to 2 C. above its ultimate limit, instead of having $\frac{1}{30}$th of a degree, the rate at which the temperature would increase in descending would be about sixty times as great as at present; that is, there would be an increase of 1° C. for little more than 1 foot of depth."

"It must be recollected that this state of terrestrial temperature, if due to the cause we are considering," that is, to the refrigeration of the globe, "could only have existed at times which, even in a geological sense, must have been extremely remote. The important peculiarity of this state of the earth would seem to consist in the simultaneous existence of a superficial temperature, and therefore of climatal conditions, very nearly the same as at present, with an internal temperature at the depth of a few hundred feet and upwards, immensely greater than at present."

With regard to the reason assigned by Poisson for the higher temperature below the surface of the earth and its changes, as cited above in Dr. Whewell's observations, Mr. Hopkins remarks: "What may have been the possible effect of this cause in the lapse of indefinite time, it is impossible to say; but I cannot understand how it could be very considerable without a totally different distribution of the group of stars to which the sun should belong, or the near approach of the solar system to some individual star. The latter hypothesis, however, would be inconsistent with the integrity of the solar system as it now exists, if we suppose the proximity to any single star to become such as to produce any material modification of terrestrial climate; and perhaps it may be difficult to conceive how the first hypothesis should escape a similar objection. At all events it may be regarded as certain that according to neither of these hypotheses can any considerable effects have been produced by this cause on terrestrial temperature within the later Tertiary period, and that we cannot thus account for the cold of the glacial epoch."

With respect to the third supposed cause of changes in the earth's superficial temperature, we need not follow Mr. Hopkins, as it does not belong to the subject immediately before us; his masterly exposition of it will be found in the papers already cited. For the special history of the glacial epoch, we may refer to Sir C. Lyell's 'Manual of Elementary Geology,' fifth edition, ch. xi. and xii. Mr. Hopkins, in continuing his researches in physical geology, has investigated the effects due to the remains of the earth's "primitive heat;" an account of his results, together with the principal known facts of the earth's internal temperature, will be given in the article TEMPERATURE, TERRESTRIAL, DISTRIBUTION OF.

REFUGE, HARBOURS OF. In the year 1840 a commission was appointed "to visit the coast between the mouth of the Thames and Selsea Bill; to examine the ports on that coast with reference to their being rendered available as places of shelter for vessels passing through the Channel in cases of distress from weather, and also as places of refuge for merchant vessels from enemies' cruisers in time of war, and more especially as to their being made stations for armed steamers employed for the protection of our trade in the narrow parts of the Channel." The commission made a report, but no measures appear to have been taken in consequence.

A select committee of the House of Commons on shipwrecks, in a report presented in 1843, recommended the formation of harbours of refuge in the British Channel, at the same time stating that they refrained from pointing out any particular situations for such harbours, from a conviction that such situations would be best decided by a body of scientific and experienced persons whose attention should be specially and exclusively directed to the subject.

On the 2nd of April, 1844, the Lords of the Treasury, on the suggestion of Sir Robert Peel, then First Lord of the Treasury, appointed a commission consisting of twelve experienced naval and military officers and civil engineers to inquire into the most eligible situations for a harbour or harbours of refuge in the Channel.

The report of the commissioners is dated August 7, 1844, and was presented to the House of Commons pursuant to an address dated March 6, 1845. The treasury minute under which the commissioners acted assigned three principal objects of investigation:—1, the selection or formation of harbours of refuge for the safety and convenience of vessels navigating the Channel; 2, that in times of war, such harbours might become stations for ships of war; 3, the expense of constructing new works, as compared with the public advantages likely to result from such works. The commissioners express their unanimous conviction that additional means of protection for the south-eastern coast of England are absolutely necessary. The harbours between Portsmouth and the Thames are only tidal harbours, and none of them are at present accessible to large steamers. The report recommends certain ports and positions as harbours of refuge and roadsteads, and certain breakwaters and military defences in connection with them, so as not only to afford shelter to merchant ships, but also to provide means by which, with the advantages of steam by sea, and railroads and telegraphic communication by land, the naval and military force of the country may be thrown on any point of the south-eastern coast in a few hours.

The following harbours and positions were especially examined:—Foreness, near the North Foreland; Ramsgate; the Brake, or Small Downs; Dover; Dungeness; Beachy Head, Eastbourne, and Seaford; Newhaven; Portland and Weymouth; Harwich Harbour. Of these places four are selected, Dover, Seaford, Portland, and Harwich, of which the commissioners estimated the expense required for the construction of the works which they recommended as follows:—Dover, 2,500,000*l.*; Seaford, 1,250,000*l.*; Portland, 500,000*l.*; Harwich, 50,000*l.* It was recommended that Dover Bay should be converted into a large harbour by means of breakwaters, with an area of 520 acres up to low-water mark, and an entrance 700 feet wide on the south front and another 150 feet wide at the east end. Its situation, four miles and a half from the Goodwin Sands, and standing out favourably to protect the navigation of the narrow seas, is peculiarly suitable as a station for a squadron of ships of war. It was recommended to construct a breakwater in Seaford Road, for the protection of trade and as a station for armed vessels. Portland, as the boundary of the narrow part of the Channel, and with reference to the Channel Islands, was recommended as another station for a squadron. The construction of a breakwater there, it was stated, would be easy, cheap, and expeditious, as a large part of the island facing the bay is crown property, and contains abundance of stone: the holding-ground is exceedingly good, and the island has abundance of water for the supply of ships. The island has great natural advantages for defence, and for the formation of a naval and military depôt during war to any extent that may be required. Harwich Harbour, formed by the junction of the rivers Stour and Orwell, was stated to have sufficient depth of water and good holding-ground over an extent capable of containing many hundred ships. By the construction of a breakwater and dredging to get rid of certain shoals, the commissioners considered that it might be converted into one of the finest and most useful harbours in the kingdom.

The military members of the commission recommended that casemated batteries should be constructed on the breakwaters themselves, supported by defences on the shore flanking the approaches to the breakwaters and harbours.

Such is a sketch of the report upon which our government has acted, and in some of its details it is so utterly ridiculous that the nation has reason to blush for the appearance our official science must bear in the eyes of foreigners; nor have the results actually attained by the works executed been much superior to the so-called scientific reasoning on which they were based. The works at Harwich have been completed, and already the laws of the tides on this part of the coast have produced the silting-up which ought to have been foreseen. At Dover, the works proceed slowly and with difficulty; but already it has been found that they have produced an alteration in the flow of the littoral current, and in the advance of the shingle, which has endangered the stability of the present shore of the west side of the bay. Any one accustomed to watch the action of marine currents must have known that such would have been the case; but then such a person would never have dreamt of judging these questions by the analysis of some bottles of sea-water. Sir W. Symonds was perfectly correct in his view of the question, and if it were necessary that a great expense should be incurred in the formation of a new harbour of refuge on this coast, it should be placed near Dungeness, or at the mouth of the Ouse, near Newhaven—without, of course, neglecting the improvement of Dover harbour. The works at Portland have been more successful than those at Dover, or at Harwich, or at Alderney; and those undertaken at Holyhead seem at present to enjoy a very equivocal reputation.

Meanwhile the want of harbours of refuge on the south and the east coast of England continues to be felt; for between the Tyne and the Humber, and between the Humber and the Thames, there is no safe refuge; nor can a vessel of great draught of water find any shelter in the British Channel between the Solent and the Thames. This is a national question; and it is one which it behoves our legislature at once to grapple with, in the interest of our now unprotected commercial marine.

The commission of 1840 recommended three places as suitable for harbours of refuge—Dover, as first in importance; Beachy Head, as second; and Foreness, as third.

(*Report of the Commissioners upon the Subject of Harbours of Refuge*, 1845.)

REGALIA, the ensigns of royalty. This term is more especially used for the several parts of the apparatus of a coronation. In England, the regalia properly so called are the crown, the sceptre royal, the virge, or rod with the dove, St. Edward's staff, the orb or mound, the sword of mercy, called Curtana, the two swords of spiritual and temporal justice, the ring of alliance with the kingdom, the armillæ or bracelets, the spurs of chivalry, and sundry royal vestments. The regalia here enumerated, all but the vestments, are preserved in the Jewel-Office in the Tower of London. Before the Reformation, in the time of Henry VIII., they were constantly kept by the religious of the abbey of Westminster; and are still presented before the king on the morning of the coronation by the dean and prebendaries of that church.

In 1649 a complete inventory was made out of the regalia in the Tower, a copy of which may be seen in the additional notes to Taylor's 'Glory of Regality,' 8vo., Lond., 1820; subsequent to which it is stated that the crowns, according to order of parliament, were "totallie broken and defaced." On the restoration of kingly government in the person of Charles II., new insignia were made for his coronation, and these, with the necessary alterations to accommodate them to their successive wearers, and to repair the injuries of time, have continued to the present day.

REGALS (*Regale*, It.), a small portable finger-organ, well known during the 16th and 17th centuries, and probably much earlier, but not now in use: though Snetzler, the celebrated organ-builder, informed the Hon. Daines Barrington, about the year 1770, that it was not then entirely lost in Germany ('Archæologia,' iii. 32); and till eighty years ago, if not later, there still existed an officer in the royal household called "Tuner of the Regalls." In Rees's 'Cyclopædia' this instrument is described as having "pipes of reeds for convenience of carriage," an error arising from a mistaken application of the organ-builder's term "reed stops," or stops in imitation of hautboys and other instruments blown through a reed.

REGENT, REGENCY. These words, like *rex*, contain the same element as *rego*, "to rule," *regens*. "ruling;" and denote the person who exercises the power of a king without being king, and the office of such a person, or the period of time during which he possesses the power. Wherever there has been hereditary sovereignty, or an hereditary kingly office, it has been found necessary sometimes to have recourse to the expedient of appointing a regent. The cases are chiefly those of (1) the crown devolving on a minor; (2) mental incapacity of the person in whom the kingly office is vested; (3) temporary illness, and incapacity in consequence; (4) absence from the realm. In the first case the regent has been called in England by the name of Protector: the latest instance being the minority of Edward VI.

The occasional absences of George I. and George II. on visits to their continental dominions rendered the appointment of regents a matter of convenience, if not of necessity. Sometimes the power was put, so to speak, in commission, being held by several persons jointly; but queen Caroline sometimes possessed the functions of regent during the absence of George II.

The nature of this part of the English constitution was however so little understood, and the practice was so imperfectly defined, that when George III. was incapacitated for discharging the duties of royalty on the first occasion when his malady became the subject of public notoriety, a question arose, on which the chief constitutional and political authorities of the time were divided in their judgment. The question was this—whether the heir apparent, being of full age, and the king's eldest son, did not become of right regent. One party, led by Mr. Fox, contended that he did. On the other side, it was maintained that it lay with parliament to nominate the person who should be regent. No regent was at that time appointed, the recovery of the king intervening. When the king was a second time incapacitated, all parties agreed in conferring the title, office, and privileges of regent on the Prince of Wales, then heir apparent. But it was done by parliament, who laid certain restrictions upon him during the first year; but in the event (which event did happen) of the continued incapacity of the king, he was to enter into the full possession of all rights and privileges of king, as if the king were dead, using however only the name of regent, not king: so that in reality the constitution of the country remained unaltered.

The time when the Prince of Wales held the office of regent is the period of English history usually called "the regency," just as "the regency" in reference to French history denotes the time of the minority of Louis XV., when the duke of Orleans was regent.

REGIMENT, a body of troops, whether infantry or cavalry, forming the third subdivision of an army; the union of two or more regiments or battalions constituting a brigade, and two or more of the latter making up a grand division or *corps d'armée*. A regiment is commanded by a colonel, a lieutenant-colonel, and a major; and when a regiment is divided into two or more battalions, each of these has, at least when complete, its own lieutenant-colonel and major. The word denotes, in general, any government; but it is now applied only to a body of men, indefinite in number, who are subject to military regulations, and immediately under the control of a colonel. The precise period when bodies of men were so designated for the first time is uncertain, yet no doubt exists that the common application of the term took place in France after the middle of the 16th century.

According to Père Daniel, the first formation of corps of troops corresponding in organisation to the modern regiments occurred in the reign of Henry II. of France; and that writer states ('Histoire de la Milice Françoise,' tom. ii., liv. xi.) that, very soon after the battle of St. Quintin (1557), in which the Constable de Montmorenci was defeated and nearly all the French infantry was dispersed, that king issued an ordonnance for the institution of seven legions of foot soldiers, each to consist of 6000 men, who were to be raised, or to do duty, in the frontier provinces of the kingdom. Each of these legions, which was commanded by a colonel, was divided into 15 companies, and to each of the latter were appointed a captain, a lieutenant, and an ensign. [COMPANY.] In this respect the legions differed from those which Francis I. had attempted to raise; for though each of the latter was to have consisted of 6000 men, it was to be commanded by six captains, one of whom only had the title of colonel; and under each captain there were to be two lieutenants and ten centurions. The legions of Henry II. were never completed to the extent prescribed by the ordonnance, and the number of companies in each was, soon after its promulgation, reduced to six.

Though these legions had most of the characteristics of a modern regiment it appears that they were quite distinct from the bodies of troops which, about the same time, bore this name; and P. Daniel conceives that the regiments were first formed from the companies, or bands, as they were called, of which, from the time of Francis I., or earlier, to that of Henry II., the infantry of France chiefly consisted. Each of these bands was commanded by a captain, who, according to Brantome, was *mestre de camp* over his soldiers; that is, he had no officer above him except the colonel-general of infantry; and the bands were distinguished by the designation of old and new, according to the dates of their formation.

The embodiment of the bands in regiments could not, it is supposed, have been later than 1562, which was in the beginning of the reign of Charles IX.; and Daniel gives in support of this opinion the words of the historians Davila and Daubigné, who, in stating the events of the years 1562 and 1563, mention by name the regiments of Picardy and of Brittany; the former writer, also, in speaking of the renewal of the civil war in 1567, says that the queen sent in haste for the colonels De Brissac and Strozzi with the *old* regiments. These last are supposed by Daniel to have been the regiments formed of the old bands above mentioned, and to have been so called in contradistinction from others which may have been more recently raised. In proof that regiments then existed independently of the legions, he remarks that, in the registers of the French army for the year 1567, mention is made of an officer who was colonel of the legion of Picardy, and of another who is called colonel of the regiment of Picardy. The regiment of French guards was raised in 1563, by Charles IX., for the defence of his person; and the legions of Guienne and Dauphiné, which had been instituted by Henry II., and disbanded in 1562, were by the same prince restored under the name of regiments, the former in 1567 and the latter in 1568. Charles also organised other regiments, and it is probable that during his reign the denomination became general. The word *terzo*, which, according to Sir James Turner ('Pallas Armata,' 1683), was in his time applied by the Spaniards to a regiment, seems to indicate that the numerical strength of the latter was considered as equal to the third part of that of some other body, as a legion.

The time when the name and institution of a regiment were adopted in England cannot be fixed with precision; but Sir James Turner, in the work above quoted, remarks that the word regiment was not then a hundred years old; and if it is meant that the word had been nearly a century in use in this country, it would follow that it was introduced about 1583, or about twenty years after it began to be used in France. In the account of the pay of the officers of the army which was raised by Queen Elizabeth in 1588, when the country was threatened with the Spanish invasion, mention is made of the colonel and lieutenant-colonel of the regiment (Grose, 'Military Antiquities,' vol. i., p. 348); and both colonel and regiment occur in Morrison's account of the army in Ireland, in 1598. From the time of that queen's reign the British army has been invariably divided into regiments; and this practice has been followed by all the other nations of Europe.

The army which it was proposed to raise in 1620 for the protection of the Palatinate was to have been formed of 12 regiments of infantry, each consisting of 13 companies, of which the first, or the colonel's company, was to be composed of 200 men, and the others of 150 men; and there were to be 50 troops of horse, each consisting of 100 men. At this time, and perhaps earlier, the word battalion came into general use to denote either the whole or some division of a regiment. Sir Walter Raleigh, in his 'History,' calls the maniples of the Roman troops at the battle of Zama small battalions. Each of the four regiments of infantry which were raised by Charles I. to serve against the Scots consisted of 1850 men; and in 1659, during the civil wars in this country, the Parliamentary forces consisted of 9 regiments of horse, each divided into 6 troops of 80 men, and 14 regiments of foot, 12 of which consisted of 1200 men, and 2 of 1100 men, all exclusive of officers. Each of the regiments was divided into 10 companies; and there were, besides the regiments, 5 bodies each containing 500 men, and 3 others each containing 300 men: these 8 bodies were called companies, and probably they corresponded to the companies or independent bands in the French army before the institution of regiments.

Soon after the Restoration all the regiments were disbanded; two of them, however, one of which is designated the lord-general's regiment of foot, and the other his life-guard of horse, were immediately (1661) re-engaged in the service of the crown; and in the same year the Scotch corps or band of 1700 men, which in the time of James I. had gone into the service of France, returned to England. (Daniel, tom. i., liv. x.) This body was then denominated the First or the Royal Regiment of Infantry: and it boasts of being the oldest regular corps in Europe.

In 1684, or near the end of the reign of Charles II., that part of the English army which was assembled near London was reviewed on Putney Heath; and a list of the officers commanding the several regiments is given by Grose (vol. ii., Appendix No. x.). The first named are three troops of horse-guards, which apparently were the lord-general's life-guards above mentioned. These were afterwards disbanded, and instead of them there were raised two troops of horse-grenadier guards; and in 1788, when the latter were reduced, the two regiments of life-guards at the head of the present list of the British regiments were raised. The second at the review was the Earl of Oxford's royal regiment of horse-guards, which was divided into eight troops; and these are the royal horse-guards which constitute the third regiment in the present list. The third was Lord Churchill's regiment of dragoons, which was divided into six troops, and which is at present denominated the First or the King's Dragoon-Guards.

The infantry consisted of the following corps, namely:—Two battalions of the royal regiment of guards, now called the Grenadier Guards; one battalion of the Coldstream regiment of guards, which regiment still bears that name; one battalion of the Earl of Dumbarton's regiment, or the royal regiment of infantry above mentioned; and one battalion of the Duke of York's, or the admiral's, maritime regiment. This last, which was named in compliment to the king's brother (afterwards James II.), was subsequently disbanded or converted into a regiment of marines. No other regiments were at the review, but there then existed the queen's regiment of foot, since denominated the queen's royal regiment of infantry: the Holland regiment, which was raised in 1665, and was so designated because it had served in that country. This was then considered as the fourth regiment of infantry, after the two regiments of guards, but it was afterwards, and is still, designated the third, in consequence perhaps of the reduction of the admiral's regiment. The same regiment is also called the *Buffs*, from the colour of the facings of the uniforms of the men. In the year 1684 a regiment of infantry was raised in Ireland; and this appears to have been the seventh, but not being considered as in the pay of England till some years afterwards, and other regiments having in the interval been raised, it became the eighteenth on the list. This is now designated the Royal Irish regiment, the epithet royal having been given to it for its gallant behaviour at the siege of Namur in 1695.

The augmentations which have since taken place in the British army consist of one additional regiment of guards (infantry), called the Scots Fusiliers; of 24 additional regiments of cavalry, making, exclusive of the guards, 25 regiments; and of infantry, as many as make 100 regiments of the line, independently of the foot-guards and the Rifle Brigade, the royal regiment of artillery, the corps of royal engineers, and the royal corps of marines. The cavalry then consists of 2 regiments of life-guards, 1 royal horse-guards, 7 regiments of dragoon guards (numbered from 1 to 7), and 18 other regiments of cavalry (numbered from 1 to 18), of which the 1st, 2nd, and 6th are dragoons, the 5th, 9th, 12th, 16th, and 17th are lancers, and the 7th, 8th, 10th, 11th, and 18th are hussars. The infantry consists of 3 regiments of foot-guards, 100 regiments of the line, the rifle brigade, and the following colonial regiments:—3 West India regiments, the Ceylon rifle corps, the Cape mounted rifles, royal Canadian rifle regiment, St. Helena regiment, royal Newfoundland companies, Gold Coast artillery corps, and the royal Malta fencible regiment. To these are now added what were the Honourable East India Company's regiments, which are now amalgamated with the royal army.

As the legions of Henry II. of France bore the names of the several provinces where they were raised, so most of the regiments composing the line of the British army are distinguished by the names of the counties or districts in which the men were enlisted: thus the 3rd is called the East Kent regiment; the 5th, the Northumberland; the 6th, the royal Warwickshire; and so on. The second of the guards, also, is called the Coldstream regiment.

For the divisions and evolutions of a regiment, see BATTALION.

REGISTER, REGISTRATION, REGISTRY. In feudal times, the owner of land, or at least the person immediately entitled to the profits arising from it, was usually the occupier, and his right was notorious among his neighbours; for in their presence possession or *seisin* of the land was delivered to him upon the spot by the lord; they signed the instrument, which was evidence of the grant, and they formed part of the lord's court, in which the grant was usually recorded. [CONVEYANCING.]

But this simple method of conveyance was in the course of time found insufficient for the more complicated circumstances of society. Land by improved cultivation became more productive, and the profits arising from it were devoted to more extensive purposes then when a large proportion of every great estate was waste. Leases of land then became more common, and as the lessee was of course in actual possession of the premises, possession ceased to be sufficient evidence of absolute property in land. Purchasers therefore now require not only proof of possession and production of the instrument by virtue of which the apparent proprietor holds the land, but also an investigation of the *title-deeds*, or documents which form the history of the land; lest any one should hereafter be produced which should be destructive of the claim of the supposed owner, and therefore of the title of those who derive their rights from him. Thus the evidence of a right to land, or to the profits arising from land, consists partly of possession, partly of the facts disclosed by the written documents or *title-deeds* relating to it, and hence partly again of the possession of the title-deeds themselves.

But there are many interests in land which exist without either of these protections. For instance, A, who is supposed by all his neighbours to be the owner of an estate which he derives from his ancestors, and has occupied since his father's death, mortgages the land to B for a sum far less than its value: he delivers the title-deeds to B, but (as is usual) retains the possession and entire enjoyment of the land by paying regularly the interest on the mortgage, and being supposed well able to pay the principal money when demanded. A then mortgages the estate a second time to C, to whom he gives notice of the prior incumbrance to B, and thus accounts for the absence of the title-deeds, which C investigates in B's hands. Here we observe that C has an interest in the land, without the security which either possession or the holding of the title-deeds gives. A has the one, B the other. We will suppose the two sums for which the estate is mortgaged to be nearly equal to its value. A borrows a further sum upon it from D, whom he informs of B's mortgage, but not of C's; and in case of dispute the Court of Chancery has to decide between the mortgagees. This would be an easy task if the rule of equity were undeviating, that priority of time gives superior right (qui prior est tempore potior est jure); but the rule that where equities are equal, law shall prevail, destroys the simpler maxim. The two last mortgagees, C and D, have, we may suppose, only an equitable interest in the land, A having granted it at the time of the first mortgage to a trustee for many hundred years, in order that the stipulations of the mortgage-deed shall be fulfilled. [MORTGAGE.] This is called creating a term of years, and it has the effect of protecting the estate from any acts done subsequently to the creation of the term, and inconsistent with the objects for which it exists. Those terms which have not merged or otherwise ceased are called *outstanding terms*. Now if, in the case supposed, D pays off B, and takes an assignment of his mortgage and of the outstanding term; if, to use the technical phrase, he "tacks" B's security to his own, he unites in himself equal equity with C, and also the legal right which the term gives him; and then he takes precedence of C, who loses the sum which he had advanced, unless indeed he too can find and obtain the assignment of an outstanding term created by one of A's ancestors antecedently to B's. But the case may be more complicated, and the means of fraud still further extended. A dies; and then comes to light a settlement made by his father, to which A was himself a party, which shows that A was entitled to the estate only during his life, that the course in which it should go after his death had been clearly defined, and that it had been conveyed, by his father and himself, to trustees for this purpose. This discovery destroys the estates of B, C, and D alike. These cases, or cases partaking of the character of these, whether the result of ignorance, or accident, or fraud, are frequent sources of litigation: they arise from the facility afforded for the concealment of deeds by the present system of conveying land; and besides the direct injury which they do to the individuals involved in them, they produce a feeling of insecurity concerning the titles to land, which, joined to the difficulty, often the impossibility, of proving titles, especially by descent, renders the alienation of land or the raising of money upon it difficult and costly. Again the advantage derived from obtaining an assignment of outstanding terms causes a conveyancer to investigate the various transfers and transmissions of them with as much care as the title to the fee; and as it may be safest to obtain the assignment of as many outstanding terms as can be procured, and especially of the most ancient, there are a variety of claims to an interest in an estate, all to be proved by the seller, and investigated by the purchaser. The deed too assigning the term is usually distinct from the conveyance of the fee, and is often of great length. Hence vast additional expense is incurred in the sale and mortgaging of land.

But supposing it to be certain that no concealed charge affects land, it may happen that the undoubted owner of it may be unable to prove his right from want of the title-deeds. N possesses an estate, which may be a small part of a much larger estate, of which the owner, M, retains the title-deeds, giving to N authenticated or *attested copies* of them, and a covenant that he, M, when required, will produce the originals. But M sells the estate, and the title-deeds pass into hands not bound by the *covenant to produce*; or he dies, and his representatives are unknown; or again, N himself sells his portion of the estate, and he cannot transfer the benefit of his covenant [COVENANT]; or, by a multitude of accidents, the deeds of some of them are lost. Instances have been known where the mere expense of giving attested copies of deeds, which a person who had contracted to sell an estate was bound to furnish, has exceeded the value of the estate.

A large proportion of the land in the country is thus unmarketable, either from the fear of latent incumbrances, or from the inability of the owner to produce his title-deeds. Prior incumbrances are indeed somewhat assisted by the doctrine of courts of equity, that if a subsequent purchaser or mortgagee has notice of the previous charge before his own transaction with the estate, he shall not by any device obtain priority over that charge. But notice does not necessarily imply knowledge. [NOTICE.] Notice may be an actual direct intimation of a fact given to the party or his agents, which is called *actual notice*; or it may be only something leading a discreet person to an investigation, which would enable him to discover the fact; thus the existence of a suit (lis pendens) touching the land affects the purchaser or mortgagee with notice. This latter class of notice is called *constructive*; it is so vague as to be easy of proof, and difficult to avoid; and one consequence of the admission of it in a court of equity is, that solicitors often think it their duty to avoid investigations which might lead to constructive notice, and so endanger the priority of their client's security.

These remarks may assist the unprofessional reader in understanding the use of a General Public Register of all deeds or instruments affecting land, in order to secure titles against the loss or destruction, or the fraudulent suppression, or accidental non-production of instruments; to simplify titles by rendering in most cases needless the assignment of outstanding terms; to protect them from the consequences of constructive notice; and to render conveyances shorter and more simple.

To a certain extent such registers have been already established in England. By the 27 Henry VIII., c. 16, it is enacted that all bargains and sales of land shall be enrolled. [Bargain and Sale.] The 2 & 3 Anne, c. 4 (amended by 5 Anne, c. 18) directs that a memorial of all deeds, conveyances, and wills concerning any lands in the West Riding of Yorkshire may, at the election of the parties, be registered; and that any conveyance or will affecting the same lands shall be deemed void against a subsequent conveyance unless a memorial shall be registered. The 6 Anne, c. 35, recites that "lands in the East Riding of York, and in the town and county of the town of Kingston-upon-Hull, are generally freehold, which may be so secretly transferred or conveyed from one person to another, that such as are ill disposed have it in their power to commit frauds, and frequently do so, by means whereof several persons (who, through many years' industry in their trades and employments, and by great frugality, have been enabled to purchase lands, or to lend moneys on land security) have been undone in their purchases and mortgages by prior and secret conveyances and fraudulent incumbrances; and not only themselves, but their whole families thereby utterly ruined;" and then the Act establishes a register of the memorials of deeds and wills in the East Riding of Yorkshire. The 7 Anne, c. 20, establishes such a register for Middlesex; and the 8 George II., c. 6, establishes one for the North Riding of Yorkshire, and provides that deeds, wills, and judgments affecting land may be registered at length, instead of the registration of mere memorials of them. In the Bedford Level too there is a registration of all deeds affecting land there. These registers, owing to the insufficiency of their indexes, and to some other defects, do not answer all the purposes which might be expected from them, and in many respects their arrangements are cumbrous and expensive: nevertheless no one has proposed to abolish them. A registration of wills has long been established, not certainly upon a good plan, since it is not always possible to say beforehand in what court a will has been proved, but nevertheless with great advantage. The Act for Abolishing Fines and Recoveries (3 & 4 Wm. IV., c. 74) substitutes for them a deed which is enrolled in the Court of Chancery. In Ireland, in the Colonies, in most of the United States, in Sweden, France, and Italy, and in many of the German States, registers are established. Nor is it found that the disclosures which a register makes of the state of landholders' property produce inconvenience, even supposing such disclosures inseparable (which they are not) from all systems of registration. It is obviously for the public benefit that the apparent extent of a person's landed property should not induce men to give him a credit to which the actual amount of that property does not entitle him.

It is clear then that if a register is established, which must be sooner or later, it ought to be taken as sufficient notice of the documents registered; and that on the other hand default of registration ought not to be remedied by any proof even of actual notice.

The Act 1 & 2 Vict. c. 110 provides that no judgment of the superior courts, or decree of the courts of equity, shall affect lands unless a memorandum thereof be registered in the Court of Common Pleas. It also enacts that no pending suit (lis pendens) shall affect the purchaser or mortgagee with notice, unless a similar memorandum is registered, this entry also being renewed every five years. The Act also requires crown debtors to be registered in the same office, and provides means for obtaining and recording their discharge from their liabilities to the crown; but the Act does not require the renewal every five years of the entry in this case.

Persons becoming purchasers and mortgagees since the passing of the Act 23 & 24 Vict. c. 38 (23rd July, 1860), are not even affected by this registration of judgments, however, unless process of execution be also issued and registered before the date of the conveyance or mortgage, and enforced within three calendar months after such registration.

REGISTER ACT. [Shipping.]

REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES. Parish registers were not kept in England till after the dissolution of the monasteries. The 12th article of the injunctions issued by Cromwell, Henry VIII.'s secretary, in 1538, directs that every clergyman shall, for every church, keep a book wherein he shall register weekly every marriage, christening, and death; any neglect being made penal. In the first year of the reign of Edward VI. (1547), ecclesiastical visitors were sent through the different dioceses in order to enforce various injunctions, and, among others, that of Cromwell with respect to parish registers. In the beginning of Elizabeth's reign this injunction was repeated, when the clergy were required to make a protestation in which, among other things, they promised to keep the register-book in a proper and regular manner. In 1694 an Act (6 & 7 Wm. III. c. 6) for a general registration of marriages, births, and deaths, was passed merely for purposes of revenue: it is entitled "An Act for granting to his Majesty certain rates and duties upon Marriages, Births, and Burials, and upon bachelors and widowers, for the term of five years, for carrying on the war against France with vigour." It is a very long Act, in which the duties are minutely set down. A supplementary Act was passed (9 Wm. III. c. 32), entitled "An Act for preventing frauds and abuses in the charging, collecting, and paying the duties upon marriages, births, burials, bachelors, and widowers." The 52 Geo. III. c. 146 (28 July, 1812), entitled "An Act for the better regulating and preserving parish and other registers of births, baptisms, marriages, and burials in England," made some alteration in the law, chiefly with reference to having the books made of parchment or strong paper, and to their being kept in dry and well-painted iron chests.

The Registration Act (6 & 7 Wm. IV. c. 86: 17 Aug., 1836), entitled "An Act for registering Births, Deaths, and Marriages, in England," came into operation July 1, 1837. By the 44th section of the 6 & 7 Wm. IV. c. 85, entitled "An Act for Marriages in England," the provisions of this Registration Act are extended to the Marriage Act, and some further facilities and regulations were given by the 19 & 20 Vict. c. 119.

The most important provisions of these Acts are the following:—A general registry-office provided in London at Somerset House. Annual abstract of registers to be laid before parliament. Register-offices to be provided in each union by the guardians, and to be under the care of the superintendent-registrar. Registrar and deputy to dwell in the district, and their names and additions to be put on their dwelling-houses. Register-books to be provided by the registrar-general, for making entries of all births, deaths, and marriages of his majesty's subjects in England, according to prescribed forms. Registrars authorised and required to inform themselves carefully of every birth and death which shall happen within their district, and to learn and register as soon after the event as conveniently may be done, the particulars required to be registered touching every birth or every death. Parents and occupiers, within forty-two days after birth and five after death, to give notice thereof to registrar; and owners and coroners to do so forthwith in cases of foundlings and exposed dead bodies. Parents and occupiers, on being required by the registrar, within forty-two days, to give all the particulars required to be registered respecting birth. Children born at sea to be registered by the captain. After the expiration of forty-two days from the birth of the child, it can only be registered within six months, on the solemn declaration of the particulars before the superintendent-registrar, who is to sign the entry, and to receive *2s. 6d.* and registrar *5s.*, extra fee; and no registration, after forty-two days, shall be made otherwise than as above, under a penalty of *50l.* Births are not to be registered after six months, and no registration after that date is to be received as evidence. Name given in baptism may be registered within six months after registration of birth, on production of a certificate by the minister. Some person present at death, or occupier of house, is required to give particulars of death, on application by registrar, within eight days; registrar to make entry of finding of jury upon coroner's inquests. Registry of persons dying at sea, containing particulars, to be kept by the captain. Registrar to give certificate of death to undertaker, who shall deliver the same to the minister or officiating person, and unless such certificate is delivered the minister must give notice to the registrar; but the coroner may order body to be buried, and give certificate thereof; and if any dead body shall be buried without certificate of registry or of inquest, and no notice given to the registrar within seven days, the party forfeits *10l.* Every register must be signed by the informant. Registrars to make out accounts quarterly, to be verified by the superintendent, and are to be paid by the guardians, as directed. Marriage register books to be provided by the registrar-general for ministers. Marriage registers to be kept in duplicate, and every entry shall be signed by the clergyman, or the registering officer, or secretary of Quakers and Jews, by the persons married, and by two witnesses. Certified copies of registers of births and deaths to be sent quarterly, and the register-books when filled, to the superintendent-registrar. Duplicates and certified copies of registers of marriages to be sent to superintendent-registrar. Superintendent-registrars to send certified copies of registers to the general register-office. Searches may be made and certificates given by the persons keeping the registers, on payment of the fees prescribed. Indexes to be kept at general register-office, searches allowed, and certified copies given. Certified copies (certificate to bear a penny stamp, to be also paid for by the applicant) given at general register-office to be sealed, and shall then be evidence without farther proof. Ministers, &c. may ask parties married the particulars required to be registered; and wilfully giving false information is perjury. The penalty for not duly registering births, deaths, and marriages, or for losing or injuring the registers is not to exceed *50l.* The penalty for destroying or falsifying register-books, or entries therein, or giving false certificates, is felony. Accidental errors may be corrected, within one month, in the presence of the parties.

Another Act was passed (1 Vict. c. 22—June 30, 1837), entitled "An Act to explain and Amend two Acts passed in the last session of Parliament, for Marriages, and for registering Births, Deaths, and Marriages, in England." This Act consists chiefly of arrangements necessary to extend and improve the provisions of the Registration Act.

Previous to the Registration Act coming into operation it was necessary to divide the country into districts of convenient size for equalizing the labours of the registrars by contracting the area where the population was dense, and extending it where the population was thin. To each district a registrar of births and deaths is appointed, and also a registrar of marriages; and in each union there is a superintendent-registrar. The registrar of births and deaths is appointed by the guardians, and is always a resident in the district in which he acts. The registrar of marriages is appointed by the superintendent-registrar, subject to the approval of the guardians.

On August 7, 1854, an Act for assimilating the registration of births, deaths, and marriages in Scotland to that of England was passed. A registrar-general was appointed, and the returns of the two kingdoms are now annually laid before parliament. The measure has not yet been applied to Ireland.

REGISTRATION. (*Scotland.*) The registration of documents in Scotland is intimately connected with the titles of real property, and with the execution of the law. It is thus divided into two distinct departments, which may be considered separately—Registration for Preservation and Registration for Execution.

Registration for Preservation, in its simplest form, is merely the preserving of an attested transcript of any deed in a public register, that thus an authentic copy may be had recourse to in case the original should be lost. Besides the regular statutory records of particular deeds, there are books attached to the several courts of civil jurisdiction, in which parties may for their own convenience register such documents as do not require by any special obligatory law to be recorded. It is a general rule that extracts from any such records may stand in the place of the originals when these are not forthcoming. In the case of deeds, of which, as will be seen below, it is not the deed itself, but its registration, that makes the completed title, an extract from the register is the proper document to be produced. In actions, however, the object of which is the annulling the deed on some legal ground, the original must be produced if it be accessible. It is usual to speak of registration for preservation as being also for publication; and in this sense, when a deed is of such a character that to make it effectual in the grantee's favour it must have been delivered to him by the grantor, such registration is in the general case equivalent to delivery. It will operate in this respect in adjusting questions of competing right, as where a father makes over to one child the property that, in case of his dying intestate, would go to another, and registers the deed. The registration of ordinary documents for preservation was sanctioned by the Act 1698, c. 4, which generally extends to registration "in any authentic public register that is competent." Besides the central register attached to the supreme court, there are others connected with the Sheriff and Corporation Courts; but it does not appear to be distinctly settled what may be, with reference to various descriptions of documents in each case, a "competent" register.

The most important of the registers for preservation is that of the "Sasines *and* Reversions," the former word expressing the act by which an estate is created or transferred in heritable (that is, real) property, the latter the attestation of the extinction of a burden (that is, of the devolution of a temporary estate on the person entitled to the remainder). This system has been gradually formed. In its present state its main operative principle is, that when a title to land appears on the register, no latent title derived from the same authority can compete with it, and that registered titles rank according to their priority; so that if A first sell his property to B and execute the proper conveyance, and subsequently sell the same property to C, if C get this title first recorded it cannot be questioned by B, who has only his pecuniary recourse against A. In pursuance of this system, in transactions regarding land, the public records are relied on as affording the means of ascertaining the character and title, and after they have searched for the period of prescription, or examined over a period of forty years [Prescription], parties can trust that there are no latent rights, and may safely deal with the person who professes to dispose of any right connected with it. The origin of this system may be traced to the commencement of the 16th century, when the notaries were required to record their proceedings in their protocols, and the other officers connected with the feudal transference of land were bound to make returns of their official acts. In 1599 an Act was passed in which an effort was made to produce regularity in these registers, by penalties. It was by the Act 1617, c. 16, that the system was founded on its right principle. The preamble of that statute bears "considering the great hurt sustained by his Majesty's lieges by the fraudulent dealing of parties who having annallied [alienated] their lands, and received great summes of money therefore, yet by their unjust concealing of some private right formerly made by them, render the subsequent alienation done for great summes of money altogether unprofitable; which cannot be avoided unless the said private rights be made public and patent to her Majesty's lieges." The Act then appoints the deeds to be registered, otherwise they are "to make no faith in judgment, by way of action or exception, in prejudice of a third party, who hath acquired a perfect and lawful right to the said lands and heritages: But (without) prejudice alwayes to them to use the said writs against the party maker thereof, his heirs, and successors." There was a material defect in this Act, that a person might have his title immediately registered, but was liable to have it superseded by any other person able to register a title on a warrant previously obtained. This was remedied by the Act 1693, c. 13, which gave the registerable titles priority not according to the date of their execution, but to that of their registration.

When property is offered for sale or mortgage, a "search" generally forms part of the titles offered for inspection to the parties treating for it. This is a certificate by the proper officer, describing all registered documents regarding that particular piece of land which have been recorded during forty years. It is remarkable that the enlightened mind of Cromwell appears to have comprehended the utility of this system, and that he made an effort to introduce it into England. We are told by Ludlow (Memoirs, I., p. 436), "In the meantime the reformation of the law went on but slowly, it being the interest of the lawyers to preserve the lives, liberties, and estates of the whole nation in their own hands, so that upon the debate of registering deeds in each county, for want of which, within a certain time fixed after the sales, such sales should be void, and being so registered that land should not be subject to any incumbrance, this word incumbrance was so managed by the lawyers that it took up three months' time before it could be ascertained by the committee."

Registration for Execution is another peculiarity of the law of Scotland, although the system of warrants to confess judgment in England in some measure resembles it. The party to a solemn deed incorporates with it a clause of registration, by which, on the deed being registered in the books of a court competent to put the deed in force, the decision of the court shall be held as pronounced in terms of the deed, and execution may proceed against the party on an extract, as if it were the decree of a court. The engagement on which such execution may issue must be very distinctly set forth. Thus, if it be for payment of money, it must be for a sum named in the deed, and not for the balance that may be due on an account arising out of the transactions to which the deed refers. This method of execution was by statute (1681, c. 20) made applicable to bills and promissory notes without their containing any clause of registration. To entitle it to this privilege, the bill or note must be apparently without flaw, must bear the appearance of due negotiation, and must have been protested. The operation of this system was much widened by the Act 1 & 2 Vict. c. 114, which extended registration for execution to the Sheriff Courts.

REGISTRY OF SHIPS. [Ships.]

REGIUS MORBUS, as used by the classical Latin authors, must not be confounded with the *King's evil*, or *Regius morbus*, of the writers of the middle ages. In the former it means jaundice (Horat., 'Art. Poet.,' 453), called also *ἴκτερος*, "morbus arquatus," and "aurugo" (or "aurigo"); in the latter it means scrofula. [Scrofula.] The derivation of the term as applied to jaundice is both uncertain and unsatisfactory. According to Serenus Samonicus ('De Medic.,' cap. 58, v. 1033)—

> "*Regius* est vero signatus nomine morbus,
> Molliter hic quoniam celsa curatur in aula."

Varro (apud Plin., 'Hist. Nat.,' lib. xxii., cap. 53, ed. Tauchn.), "*Regium* cognominatum morbum arquatum tradit, quoniam mulso curatur;" "Scilicet" (says Doering, ad Horat., *loc. cit.*), "*mulsum* (vinum melle conditum) pertinet ad delicias, quas reges imprimis et beatiores appetunt et facile sibi comparare possunt." The same derivation is given by Celsus ('De Medic.,' lib. iii., cap. 24), who says the cure is to be attempted by various kinds of exercises: "Lecto etiam et conclavi cultiore, lusu, joco, ludis, lascivia, per quæ mens exhilaretur, ob quæ *regius* morbus dictus videtur." Blancardus (*Blanckaert*, or *Blankaard*) in his 'Lexicon Medicum,' is rather inclined, "ab *auro*, metallorum *rege*, denominationem statuere, sicut et *Aurigo*, ab *auri* colore." Dr. Good ('Study of Medicine') says, "the meaning of *Regius*, as expounded by Celsus, will, I apprehend, content very few;" he then remarks that this and the two other Latin names of the disease (*Arquatus Morbus* and *Aurugo*) "are not indeed univocals, but very clearly equivalents, and equally import *gold*, *golden crown*, *golden bow*, or *circumfusion*; the colour of the disease, and its encompassing the body." Each of these derivations appears somewhat far-fetched and unsatisfactory, and the term is probably one of those of which no plausible explanation can be given.

REGRATING. A regrator is defined (6 Ed. VI., c. 14) to be one who buys in a fair or market the various articles specified by the Act, which are principally articles of provision, and sells them again in the same or in any other fair or market within four miles. That statute and others providing certain penalties for such acts have all been repealed by 12 Geo. III., c. 7.

REGULAR CLERGY [Clergy.]

REGULAR FIGURES, POLYGONS, SOLIDS, POLYHEDRONS. We have here to add to what is said in Polygon and Polyhedron all that concerns the regular figures or solids, not as to their general properties, but as to the proportions of their parts and the mode of describing them. We shall take first the plane figures, and then the solids.

A regular polygon, meaning one of which all the sides are equal and all the angles are equal, may have any number of sides from three upwards. The Greek terms trigon, tetragon, pentagon, hexagon, heptagon, octagon, nonagon, decagon, undecagon, dodecagon, are in use (except the first two) to express polygons of three, four, &c., up to twelve sides. The term quindecagon is in use to express the polygon of fifteen sides.

Let the polygon be described, having n sides: let its side be a, its area V, and let r and R be the radii of the inscribed and circumscribed circles. The formulæ which connect these quantities are then as follows:—Let ν stand for the nth part of 180°, then

$$a = 2\,\mathrm{R} \sin \nu = 2r \tan \nu,$$

$$\mathrm{V} = \frac{na^2 \cot \nu}{4}$$

which are enough to determine the remaining three of V, a, R, r, when one of them is given. To facilitate the determination and construction of any regular polygon not having more than 12 sides, we take the following table from James Dodson's 'Calculator' (1747), which is correct to every figure so far as we have thought it necessary to examine it. The author generally corrected errata with his own pen in every copy, and the one before us has his corrections:—

When the Length of Side = 1.

No. of Sides.	Radius of Circumscribed.	Radius of Inscribed.	Area.

12	0·2988585	0·5773503	0·5576775

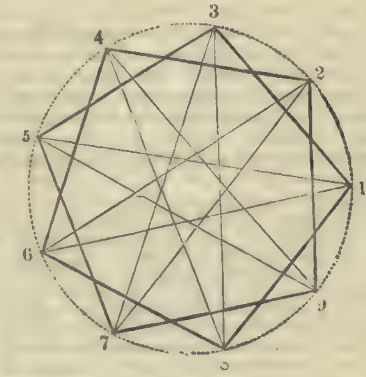
By means of these tables the construction of any figure is immediately reduced to a short calculation, the drawing of a circle, and setting off equal chords on that circle, the compasses and a scale of equal parts being all the instrumental aid necessary. It is required to construct, for example, a regular heptagon, or figure of seven sides, with an area of 225 times the square on one of the larger divisions of the scale. The side and radii must therefore be increased in the fourth table in the proportion of $\sqrt{225}$ to $\sqrt{1}$, or of 15 to 1. And

$·5245813 \times 15 = 7·8687$ side.
$·6045183 \times 15 = 9·0678$ rad. circum.
$·5446520 \times 15 = 8·1698$ rad. inscr.

If the two circles be carefully drawn from the same centre, and chords equal to the side taken off, the compasses will be found to be carried exactly seven times upon the larger circle, and the chords, being drawn, will be found to touch the inner circle, and any little error of construction will be better shown by failure of touching the inner circle correctly than by any other means.

The above presumes that it is desired to proceed as accurately as possible; but for rough work, and when the circumscribed circle is known, the proportional compasses, or even a common pair of compasses and trial, will succeed perfectly well. The proportional compasses have a scale for the adjustment of the pivot in such manner that when the opening at one end is the radius of a circle, that at the other end shall be the side of the inscribed polygon of a given number of sides.

The regular polygons hitherto treated have been those of Euclid, without any re-entering angles. The star-shaped polygons (which, though equilateral and equiangular, do not come within Euclid's definition) are described by drawing a regular polygon of the same number of sides, and drawing successive diagonals so as to cut off a number of sides which is prime to the number of sides of the polygon.



Thus, if 12, 23, 34, &c., be the sides of a regular nonagon, or nine-sided polygon, it follows that there are two regular star-shaped nonagons, one made by diagonals which cut off 2 or 7 sides, and one made by diagonals cutting off 4 or 5 sides. Diagonals cutting off three sides would give three equilateral triangles, but no nonagon at all. These nonagons are 1357924681, and 1594837261. Star-shaped dodecagons are also only one in number, since 5 and 7 are (except 1 and 11, which would only give the dodecagon of Euclid) the only numbers less than 12 which are prime to 12. But a regular polygon of 13 sides has 5 star-shaped polygons, made by diagonals cutting off 2 and 11, or 3 and 10, or 4 and 9, or 5 and 8, or 6 and 7 sides.

We now come to the subject of regular polyhedrons, presuming the reader to know the contents of the article POLYGON AND POLYHEDRON. A great many properties of these solids have been investigated, but as they are of little use, it will be unnecessary to do more than give tables for constructing them of given dimensions. Let a solid be contained by f faces, each of which is a regular polygon of n sides. Let c be the number of corners or solid angles, e the number of edges, and m the number of angles which meet at a corner. Then since there are c corners with m angles at each, the number of edges, counting each edge as often as it meets a corner, is mc; or, as each edge meets a corner twice, $\frac{1}{2}mc = e$, the number of distinct edges. Again, since there are f faces, of n sides each, and every edge is the union of two faces, we have $\frac{1}{2}nf = e$. But $f + c = e + 2$, or

$$\frac{2e}{n} + \frac{2e}{m} = e + 2, \text{ or } e = \frac{2mn}{2m + 2n - mn}$$

which must be a whole number. And neither m nor n can be less than 3, nor greater than 5, for there are no figures of fewer sides than 3, and [POLYGON AND POLYHEDRON] spaces cannot be inclosed entirely by figures of more than five sides. The rest follows from the properties of conjugate solids in the same article.

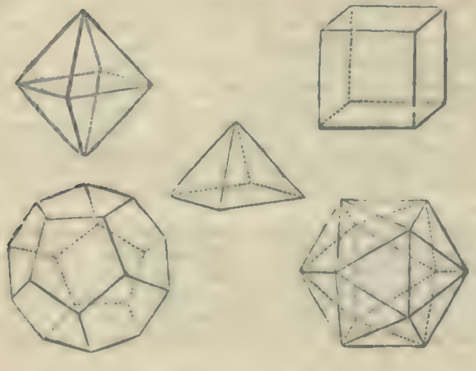
Let $n = 3$, or $e = 6m \div (6 - m)$. This is a whole number (1) when $m = 2$; this must be rejected: (2) when $m = 3$, giving $n = 3, m = 3, e = 6$,

$f=4$, $c=4$, or four triangles; we have here the regular tetrahedron, or triangular pyramid: (3) when $m=4$, giving $n=3$, $m=4$, $e=12$, $f=8$, $c=6$, or eight triangles; we have here the regular octohedron: (4) when $m=5$, giving $n=3$, $m=5$, $e=30$, $f=20$, $c=12$, or 20 triangles; we have here the regular icosahedron.

Let $n=4$, or $e=8m \div (8-2m)$. This is a whole number (1) when $m=2$; which reject: (2) when $m=3$, giving $n=4$, $m=3$, $e=12$, $f=6$, $c=8$, or six squares; we have here the regular hexahedron, or cube, the only one of its kind.

Let $n=5$, or $e=10m \div (10-3m)$. This is a whole number (1) when $m=2$; which reject: (2) when $m=3$, giving $n=5$, $m=3$, $e=30$, $f=12$, $c=20$, or 12 pentagons; we have here the regular dodecahedron, the only one of its kind.

We have thus the five regular solids, and have shown that there can be no others.



The centre of a regular polyhedron is obviously the point of intersection of lines drawn from the corners, each inclined at the same angle to all the edges which meet it. The radius of the circumscribed sphere is the line drawn from any corner to the centre; that of the inscribed sphere is the perpendicular let fall from the centre upon any of the faces.

The following table answers to that for polygons, and is taken from the same source:—

When the Side = 1.

Solid.	Radius Circumscribed.	Radius Inscribed.	Superficies.	Volume.
Tetrahedron . .	0·6123724	0·2041241	1·7320508	0·1178511

REGULAR POLYGON, REGULAR SOLIDS. [Regular Figures.]

REGULATORS OF MOTION. Fly-wheels are the means usually employed to render the movements of machines as nearly as possible uniform; and the nature as well as the applications of these will be described under Wheels, and under Steam-Engine. Pendulums, as regulators of motion for clock-work, are described under Pendulum; and the *Governor*, by which the supply of steam is regulated, will be described under Steam-Engine. Some account of air-vessels for regulating motion in the tread-wheels, which are employed in prisons, has been given under Air-Vessel, and it may be added that a particular kind of fly has been occasionally used for the like purpose. This consists of a vertical rod or shaft about 20 feet high, carrying at its upper extremity, on opposite sides, a long rectangular frame, which is provided with shutters turning on hinges; by the revolution of the shaft these frames turn round horizontally; and the shutters being connected with two governor-balls by means of wheel-work, when the motion of the tread-wheel becomes too rapid, the diverging balls cause the shutters to close, and thus the resistance of the air diminishes the velocity. Should the movement of the tread-wheel become too slow, the balls collapsing allow the shutters to open, when the resistance of the air is diminished and the velocity of revolution increases.

RE'GULUS. A line drawn from the pole-star, not through the two pointers, but between them and the five secondary stars of the Great Bear, which lie near them, will pass through the bright star called α Leonis, or Cor Leonis (the lion's heart). By Ptolemy and other Greeks it was called *βασιλίσκος*, whence comes the Latin name Regulus, a word which is the diminutive of *rex*.

REINSCH'S TEST FOR ARSENIC. [Arsenic, Detection of.]

REJOINDER. [Pleading.]

RELAPSING FEVER. [Blood, Diseases of the.]

RELATION (Mathematics). What we here mean by this word would have been explained in the article Equation, if we had confined ourselves to the explanation of arithmetical algebra; but having in the articles Algebra and Operation endeavoured to give higher views, we are induced to insert the present article by remembering that the difficulties of such a subject are of very different kinds to different persons, insomuch that any point of view may be usefully taken with reference to some minds, and any detail upon a fundamental notion may remove misapprehension in one quarter or another.

All reasoning is the discovery of relations which are not evident from those which are; or rather, since the proposed result is sometimes evident in itself, reasoning is the establishment of one relation as a necessary consequence of others. The term relation would be difficult to define in a manner satisfactory to all; it is enough for our present purpose to say a relation exists between any two objects, whether of sense or intellect, whenever they have anything in common; that is to say, the common point, whatever it may be, may be made the means of referring one to the other, or bringing our thoughts from one to the other, so as to think of both at the same time, and to compare the two. All the manifold senses of the word may be derived from this one: the relationship of blood implies a common ancestry; the relationship of office, common duties. In mathematics, the relation of greater, equal, or less, implies that one of the magnitudes is the same as to quantity with part or all of the other, and so on. Sameness in every respect would constitute identity; sameness in one or more respects, relation. The triangles in Euclid, i. 4, are by hypothesis related in a given manner in three particulars: a change of place shows that they can be made identical; that is, their difference before the change of place was difference of position only, not at all of form; in all that can distinguish one triangle from another, except its position in space, they are identical. We do not quarrel with the phrase that they are the same triangles differently placed, because sameness is understood with a reservation, and the preceding means that they are the same except in difference of place.

In an algebraical expression we may have to consider its meaning, form, magnitude, source, mode of derivation, and properties. The meaning depends upon the fundamental definitions which are employed and the form; the form, upon the arrangement of the symbols; the magnitude, when magnitude is signified, upon the form and the particular values given to the symbols; so that these various sources of relation are closely connected with one another. The fundamental meaning of the sign = implies equality of quantity or magnitude, and some insist that it shall always retain this meaning. There can be no objection to any one insisting on this point for himself; but the learner—who, if he be wise, will learn all languages with the majority, even though he should afterwards teach with the minority—must make himself accustomed to various uses of this sign, as follows:—

1. The sign = means that on one side we have an operation to be

performed, and on the other side the result of performing that operation by general rules, as in

$$(x+a)\,(x-a)=x^2-a^2 \qquad a^7 \div a^7 = a^{\circ}.$$

Whenever the resulting form is intelligible both in form and magnitude, the resulting relation is equality of magnitude under difference of form, independently of the particular values of the symbols; but when the result is unintelligible, as is the second of the preceding results when first obtained, this relation no longer exists: the process described in INTERPRETATION makes it exist. In all such cases the relation is that of sameness of value and properties, sameness in fact of everything but form; and the relation is independent of the magnitude of the algebraical symbols.

But did no relation exist in $a^7 \div a^7 = a^{\circ}$, until we had interpreted the then unknown symbol a° to mean unity? We answer, that a relation did exist—namely, sameness of properties. The value of the first side is unity; the unknown symbol of the second side would be found on trial to have all the properties of the unit, when common algebraical rules are applied. If we were to refuse the interpretation, and consider a° as a self-contradictory symbol, we could not deprive it of the properties of a unit, or rather, we could not deprive ourselves of the knowledge that the algebraical use of it would produce the same results as the algebraical use of a unit.

To the same head may be referred the meaning of =, as connecting an infinite series with its finite source of development (or its involepment). Arithmetical equality may not exist, for the series may be divergent; but between the development and its involepment exists the relation of sameness of properties, and the relation of sameness of source. The infinite series $1-1+1-1+$, &c., is equated to half a unit; that is, the sign = is put between $\frac{1}{2}$ and $1-1+1-1+$, &c., *ad inf.* The relation of sameness of magnitude has no existence, for $1-1+1-$, &c., *ad infinitum*, furnishes no definite idea of magnitude; but in properties, the two are the same.

2. The sign = means the relation of sameness of magnitude, without reference to form; and in this sense its use generally imposes conditions on one or more of the symbols employed, and always does so unless when the sign might also truly have the meaning described under the first head. Thus $2x+3=x+4+x-1$ imposes no condition on the value of x, because the first side is only a more simple performance of the operations indicated on the second side; but $2x+3=21-x$ is the assertion of a relation existing which is not true of the forms, and is not generally true as to the magnitudes. The condition $x=6$ is necessary to the truth of the relation asserted to exist. Relations of this sort, under the name of equations, are the first which meet the student at his entrance into algebra; and he frequently has a subsequent difficulty in extending the use of the symbol =. Being accustomed to see it impose conditions of magnitude, he cannot easily cease to imagine that it always does so; and he looks upon the two equations

$$\epsilon^x = 1+x+\frac{x^2}{2}+\text{\&c.}, \qquad \text{and } x+1=2,$$

as things of the same kind, differing only in complexity. To prevent this, the distinction between *identical* equations (so called),—namely, assertions of the relation described under the first head,—and equations *of condition*, should be strongly marked at the outset of his course. It would even be wise to use somewhat different symbols for the two relations: thus = might denote the first described relation, and = the second. The learner might drop the slight distinction which exists between the two symbols when he finds himself able to do without it; but we are satisfied that those who had once learned to use it would never think the time was come when they might safely drop it.

3. The sign = means the relation of algebraical identity between the results of different operations, when the symbols are not symbols of magnitude, but of OPERATION: that is, it asserts the relation of sameness of effect between the two operations which are written on one side and the other of it. And here it is in truth used in the first sense described, the difference being in the meaning of the symbols, not in that of the relation. And here again there is the distinction between the case in which the relation is explicable from definitions, and that in which it requires interpretation. Thus, in the relation $(1+\Delta)^2=1+2\Delta+\Delta^2$, we can prove and verify that the operation $1+\Delta$ is of that sort which, if performed twice following, will yield the same result as the sum of the results of the operations 1, 2Δ, and Δ^2. But when, having established, as in the article cited, a right to the use of all the ordinary transformations of algebra, we come to $1+\Delta=\mathrm{E}^{\mathrm{D}}$ and $\mathrm{D}=\log\,(1+\Delta)$, we have results of which the first side only is explicable, and the second requires interpretation. It might be satisfactory to consider such symbols as $\log\,(1+\Delta)$, &c., in no other light than as abbreviations of the series into which they might be developed in common algebra; but as such a use of interpretation seems to a beginner to be more arbitrary than it really is, we may point out how to make the passage in a somewhat more guarded manner, presuming the reader to be perfectly well acquainted with the results of the article OPERATION.

If A, B, &c., stand for symbols of operation, then $\mathrm{A}+\mathrm{B}$, $\mathrm{A}\,\mathrm{B}$, $\mathrm{A}\div\mathrm{B}$, are compound results of operation, which are capable of and actually receive a distinct definition. Similarly, A^n is also deducible in meaning from the definition when n is any number, whole or fractional, positive or negative; but A^{B}, where B is also a symbol of operation, cannot be immediately explained from definition. But it is to be remembered that an algebraic quantity may be susceptible of different definitions, though really amounting to the same definition. Sometimes nothing more than a mere change of the form of words will render a notion capable of being rationally extended further than it could have been before the change was made. For instance, in FRACTIONS, we understand the division of 7 into 3 equal parts, and into 4 equal parts; but a division into $3\frac{1}{2}$ equal parts is a set of words without meaning. But if we only speak of taking parts of which three make 7, and other parts of which four make 7, it is perfectly easy to imagine parts such that three parts and half a part make 7. Can we not, then, take such a method of defining A^{B} as, without in any way altering its common meaning, shall present that common meaning in a form which will be intelligible when A and B are symbols of operation?

In BINOMIAL THEOREM it is proved that the equation $\phi x \times \phi z = \phi\,(x+z)$ can only be satisfied for all values of x and z, by $\phi x = c^x$ where c is independent of x.

If, then, we propose the equation—

$$\phi x \times \phi z = \phi(x+z) \quad , \quad \ldots\ldots \; (1)$$

the only solution must be c^x. It is easy enough to show that—

$$c^x \,.\, c^z = c^{x+z};$$

the proof referred to shows that c^x is the *only* solution of this equation. If z and x be symbols of operation, and if by ϕx we mean a combination of operations performed with x, and by $\phi x \,.\, \phi z$ the result of successively performing the operations ϕz and ϕx, we may denote by y^x an operation which is such, that calling it ϕx, the successive performance of ϕx and ϕz is equivalent to that of $\phi(x+z)$; and that, calling it ψy, the successive performance of ψy and ψz is equivalent to that of $\psi(yz)$. If we want to define the particular operation A^x, we must add to the equation (1) the following:—

$$\phi(1) = \mathrm{A}.$$

Thus, let it be the definition of ϵ^{D}, D being a symbol of operation, that we have here an operation such that if it and $\epsilon^{\mathrm{D}'}$ were successively performed, the result would be the same as if $\epsilon^{\mathrm{D}+\mathrm{D}'}$ were performed at once; this last symbol implying that the operation $\mathrm{D}+\mathrm{D}'$ is used in the same way as D in the first. Moreover, let it be understood that if D were 1—that is, if the operation D produced no alteration in the function operated on—the result of ϵ^{D} would be simple multiplication by ϵ. There is nothing in this definition which is unintelligible, though there is something unknown. An operation is defined by means of itself; the definition must then be developed before its object can be understood, but it is not the less a definition—that is, a description of some one operation, and a distinction between it and every other. Thus, in common algebra, the magnitude of x may be defined by an equation, say $x=12-x$. Here x is only given in terms of its unknown self, but it is not the less defined to be 6, and nothing but 6. When the step above described has been made, it is (owing to the demonstrated connection of the rules of common algebra with those of the calculus of operations) the same process to prove that—

$$\epsilon^{\mathrm{D}} = 1+\mathrm{D}+\frac{\mathrm{D}^2}{1\,.\,2}+\ldots\ldots$$

when D signifies an operation, as when it signifies a quantity.

The definition of log D is that this operation is the inverse of ϵ^{D} with respect to D; so that log ϵ^{D} means D. Those functions which in common algebra are trigonometrical [SINE] cannot be defined in the subject of which we are speaking otherwise than by reference to the well-known exponential forms. Thus, D denoting an operation—

$$\text{Cos D means } \frac{1}{2}\left\{\epsilon^{\mathrm{D}\sqrt{(-1)}} + \epsilon^{-\mathrm{D}\sqrt{(-1)}}\right\}$$

$$\text{Sin D means } \frac{1}{2\sqrt{(-1)}}\left\{\epsilon^{\mathrm{D}\sqrt{(-1)}} - \epsilon^{-\mathrm{D}\sqrt{(1-)}}\right\}$$

It might perhaps be said that though we have constantly used the word relation, yet we have considered nothing but identity, that is, either identity of magnitude, form, process, or properties; but that the term in common life refers to something short of complete identity, frequently meaning mere connection, and sometimes only analogy, or even nothing more than resemblance. We answer, that relation always refers to identity of some sort. For example, there is a relation between the position of the sun and moon and the state of the ocean. Here the word means merely a connection; but this connection involves an absolute identity: having given the position of those heavenly bodies with respect to any place, together with the direction and quantity of their motions, the height of the water at that place is connected with the quantities which express those positions and motions by an equation or a mathematical identity. Resemblance again means identity in some respect, or near approach to identity: analogy, a term generally applied to relations of similarity, will be found to admit of the word sameness being used instead of similarity. Thus, when we say that substance is formed from *substare* in a manner similar to that in which distance is formed from *distare*, the analogy asserted is one of absolute identity (of mode of derivation).

Reasoning by analogy is either the same thing as common reasoning; or else analogy is but another word for induction. If A give B, and C have something in common with A, it may be a necessary consequence that C gives D; D being connected with C in the same manner as B with A. But this happens only when the following of B from A is a necessary consequence of that which A and C have in common, and of that only: in which case the deduction of D from C by analogy with the deduction of B from A, is only an assertion of the possibility of applying the same mode of proof to that part or property of C which was previously applied to the same part or property of A. But when we conclude by analogy of a horned animal that it is not carnivorous, as it is said; that is, when we conclude that the horned animal of which we speak will resemble all other horned animals which we know, in every point in which they resemble each other, we apply no other process than the establishment of a highly probable result by induction.

Reasoning by pure analogy, is then, not absolutely demonstrative reasoning, except in the case above described, in which we want no new name for the process. But attention to analogy in the structure of definitions, and in the route of investigation, is necessary to the success of many inquiries, and gives clearness and saves time in all. Indeed it may be taken as a maxim that whenever there is any species of resemblance pervading the results of two branches of inquiry, there ought to be a reason for that resemblance in the nature of the two subjects, expressed by a resemblance of the notations used; and this reason ought to be made prominent and insisted on.

For instance, we have two distinct *algebras* [ALGEBRA], which, for temporary distinction, we may call arithmetical and geometrical, using the same symbols in the same manner, but proceeding upon meanings given to those symbols which appear altogether different. The only reason given to the student in the article cited, to justify the definitions of the latter, or geometrical algebra, was that they would be found to answer a certain purpose, namely, to make all theorems in the earlier algebra true, when no other alteration was made than that of the meanings of the symbols. It is now to be asked, why have the new definitions that property? what relation have they to the old ones which gives the results of the two a perfect community of form? The answer to this question is not very difficult; but it will require us first to consider what are the operations of common arithmetic, and how they are to be described in terms of the simplest notions of the science.

The fundamental operations of arithmetic are addition, subtraction, multiplication, and division. Of these we may make the definitions of subtraction and division follow from those of addition and multiplication: thus subtraction is the process which destroys the effect of addition, and division that which destroys the effect of multiplication.

The fundamental ideas of arithmetic are, first, that absence of all magnitude which must precede the consideration of any particular number; secondly, the particular magnitude which we choose for repetition, and to which we refer other magnitudes. Nothing and unity are the names of these ideas; and 0 and 1 are their well-known symbols. The first, 0, reminds him who uses it, of the state in which he is antecedently to thinking of any number; the second, 1, of the successive accessions by which he passes from one object of consideration to another. If 0 do not present itself before we can think of any number, it is that we avoid it by an act of memory; but if, for instance, a person had forgotten what seven was, as a young child might do in learning arithmetic, he would be obliged, beginning from 0, to construct 7 by repeated accessions of a unit each time.

Now addition of one number to another is a process which merely puts a number in the place of *nothing*, and proceeds to count from that number in the same manner as when we form the number to be added from 0. Thus to add b to a we do with a what we should have done with 0 to form b: to add 4 to 3, we do with 3 what we should have done with 0 to form 4. If this last operation were performed on the fingers, we should first complete three, and then count the fingers which make four from and after the completion of the three; thus—

$$4=0+1+1+1+1$$
$$3+4=3+1+1+1+1$$

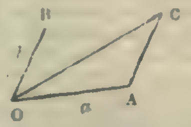
This definition of addition, namely, that "$a+b$ is a direction to do that with a, which would give b if a were nothing," will now be put by for a moment, until we are ready to apply it in the construction of the new algebra.

Multiplication of one number by another is a process which puts a number in the place of *unity*, and proceeds to use that number in the same manner as we use unity when we make another number. Thus, to multiply a by b, we do with a what we should have done with unity to make b; to multiply 3 by 4, we do with 3 what we should have done with unity to make 4. Thus,

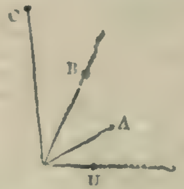
$$4=1+1+1+1,$$
$$3\times 4=3+3+3+3.$$

The definitions of subtraction and division are then obtained, as before described, by the supposition of inverse operations, or operations destructive of the effects of addition and multiplication.

In consequence of the preceding considerations, we shall pass from the limited to the more extended algebra without anything of any arbitrary character, except only the choice of a meaning for the fundamental symbols. In arithmetic, the symbols a, b, c, &c., mean simply numbers; let their meaning in the geometrical algebra be not numbers but lengths, or if numbers, let them be numbers of lengths, a given length being taken as the unit. And let each symbol be expressive not only of a length, but of a length in some particular direction; by which we mean that two lines are not to be denoted by the same symbol, unless they have not only the same lengths but the same directions.



This one fundamental change in the meaning of the things signified by letters is now all that need be made; for all the rest is absolutely the same as in arithmetic. For example, what is $a+b$? Let O A and O B be the lines represented in length and direction by a and b; having completed O A, that is, having passed from O to A through the proper length and in the proper direction, do that which would have given O B if O A had been nothing, or if A had been at O; that is, draw A C equal and parallel to O B, and in the same direction. The point C thus attained terminates a line O C, the length and direction of which is therefore to be denoted by $a+b$, since every process is to resemble that of arithmetic in everything but the meaning of the objects of calculation.



Again, required the meaning of $b\,a$? We must now choose a length and direction which is to be represented by 1; let this be O U. We are now to do with O A or a what we should have done with O U to make O B. Suppose for simplicity that O B is double of O U. To turn O U into O B, we must double its length, and let it revolve through a certain angle U O B. Do this with O A; that is, double its length, and make it, thus doubled, revolve to the position O C, so that the angles U O B and A O C are equal. Then O C must be that which is represented by $b\,a$; and the angle U O C is the sum of the angles U O B and U O A.

If we examine the fundamental definitions of the geometrically defined system of ALGEBRA, we shall find that we have here described enough to deduce them all, and that we have done it by pure analogy. But also remark that analogy here means nothing but an identity of process; we have described the processes of addition and multiplication in terms which connect them so closely with the objects to which they are applied, and at the same time make the process so distinct from the subject-matter of the process, that when we change the subject-matter, we can still preserve the process. If then any other subject-matter could be found, such that, with reference to meanings of a and b derived from it, $a+b$ and $a\,b$ could be consistently defined, or rather deduced, from 0 and 1, a new application of the rules of algebra would follow.

In the calculus of operations, the same steps might be made; and when this branch of algebra consisted of nothing but the separation of the symbols of operation and quantity in an arbitrary manner [OPERATION], analogy was the species of relation by which the deduction of results from this separation was connected with the results of common algebra. But this analogy was only the guide to the results, and not the proof of them: it became a proof when it was shown that the validity of the common algebra itself depended, not upon the whole meaning of the symbols, but upon that part of it which was preserved in the meanings of the symbols of operation.

RELATION (Logic). In the article LOGIC (cols. 345, 346) we have contended that any composition of relations is syllogism, and have stated our objection to the mode used by logicians of reducing such compositions to *their* syllogism, in which the only relation is identity. Without further controversy we shall proceed to statement, and nothing more, of a few heads of the general doctrine of syllogism. Those who desire more must consult a paper on the logic of relations, which will appear in vol. X., p. 2, of the Cambridge Philosophical Transactions.

Let L and M denote relations: X, Y, Z individual objects of thought, classes or attributes, it may be, considered as units of thought. Let LX denote anything which is an L of X, in the relation L to X.

Let l, m, denote not-L, not-M, so that lX contains all which is not related to X in the relation L. Let L and l be called *contrary* relations. Let X . . LY denote that X is an (some one) L of Y: and let X . LY denote that X is not any L of Y. Here X is the *subject*, and Y the *predicate*, of the relation. Hence X . . LY and X . lY are of identical meaning. Let an L of an M be signified by LM.

Let L^{-1}X (which may be read *L-verse* of X) be the *converse* relation of X: that is, Y . . LX and X . . L^{-1}Y have the same meaning: and Y . . LX, Y . lX, X . . L^{-1}Y, X . l^{-1}Y, are all of one meaning.

Let LM′ signify an L of every M, and L,M an L of none but Ms. Let these accents be called signs of *inherent quantity*. Note that contraversion of both relations, the sign of inherent quantity being shifted, makes no alteration of meaning: thus LM′ is l,m, and L,M is lm′.

Converses of contraries are contraries. Contraries of converses are converses. The contrary of a converse is the converse of the contrary. Thus l^{-1} and L^{-1} are contraries: not-L and not-L^{-1} are converses: and not-(L^{-1}) is (not-L)$^{-1}$.

If every L be N, every L^{-1} is N^{-1}; but every n is l, and every n^{-1} is l^{-1}.

The converse of a compound is the compound of the converses in inverted order, the sign of quantity, if any, being altered in meaning. Thus LM and $M^{-1}L^{-1}$ are converses, as are LM′ and $M_{,}^{-1}$ L^{-1}, and also L,M and $M^{-1}L^{-1\prime}$.

The contrary of a compound is formed by contraverting one component, and either adding the sign of quantity to, or removing it from, the other. Thus the contrary of LM is either of the identicals L,m and lM′; of L,M, Lm; of LM′, lM.

When a compound of two relations is contained in a third, the same is true if the contrary of the third and of one of the components change places, the remaining component being converted. And the three results are identical. Thus it is the same thing to say that every LM is N as to say that every L^{-1}n is m, or that every nM^{-1} is l.

A syllogism is the deduction of a relation between two terms from the relation of each term to a third. The first figure of the logicians is that of *direct transition:* X related to Z through X related to Y and Y to Z. The fourth figure is that of *inverted transition:* X related to Z through Z to Y and Y to X. The second figure is that of *reference to* (the middle term): X related to Z through X to Y and Z to Y. The third figure is that of *reference from* (the middle term): X related to Z through Y to X and Y to Z.

Each figure has four *phases*, distinguished by the qualities of the premises. If + and − signify affirmative and negative, the four phases are + +, − +, + −, − −: and these are the primary phases of the four figures. The others are as in the following table:—

Figure.	Phase. 1.	2.	3.	4.
I.	+ +	− +	+ −	− −
II.	− +	+ +	+ −	− −
III.	+ −	− +	+ +	− −
IV.	− −	+ −	− +	+ +

In the first phase of the first figure inference is simple composition: thus X . . LY and Y . . MZ give X . . LMZ. In every other case inference must be made by reduction into the first phase of the first figure. Thus III. 2 has the premises Y . LX, Y . . MZ, or X . . l^{-1}Y, Y . . MZ, giving X . . l^{-1}MZ. To give the conclusion a negative form, we must write X . L^{-1}M′Z, or X . $l_{,}^{-1}$mZ, the first of which is the more natural, since the concluding relation is formed from those in the premises, without contraversion.

A relation is *transitive* when being compounded with itself, it reproduces itself; that is, L is transitive when every L of L is L. If one relation only be employed, and that one transitive, and if we allow only those phases in which the conclusion is either the relation or its converse, the syllogisms with both premises negative are no longer legitimate. And the rule of distribution is as follows; the primary phase of each figure contains no converse: when one premise differs in quality from that in the primary phase, the other premise must have a relation converse to those of that premise and the conclusion: when both premises differ in quality from those of the primary phase, the conclusion must have a relation converse to those of the premises. Thus III. 2 differs in both premises from III. 1; accordingly Y . LX, Y . . LZ gives X . L^{-1}Z: but IV. 3 differs only in the second premise from IV. 1; and Y . L^{-1}X, Z . . LY gives X . LZ.

These hints may be useful, in connection with the article LOGIC, to give an idea of the general syllogism of composition of relations, and to throw that light upon the meaning of the ordinary syllogism which the general always throws upon the particular, an advantage which has hitherto been denied to logic.

RELATIVE MAGNITUDE. [RATIO.]

RELATIVE MOTION. [MOTION.]

RELATIVE PRONOUN. The relative pronoun is so called because it relates to some object mentioned just before, which object is usually termed the antecedent. The English language possesses two words for the relative pronoun, *who* or *which*, and *that*. The word *what* must also be regarded as a relative, for it evidently contains the same root as *who* and *which;* it is generally used in the sense of *that which*, as "Let them say *what* they will." The terms, *who*, *which*, and *what* are also used as interrogatives, and contain the same root as the Sanskrit *ka-s*, the Greek ὅ-ς, the Latin *qui*, the Gothic *hver*, &c. The term *that* is evidently the same word as the demonstrative pronoun. In the same way we find that the Greek article, which was originally a demonstrative pronoun, is also used as a relative; and the German language likewise possesses two forms for the relative, *welcher* and *der*, the latter of which is also a demonstrative, and is the same word as the English *that*. According to Bopp ('Vergleichende Grammatik,' p. 553), the relative in Zend is also used as a demonstrative.

In English the relative is not unfrequently omitted. Thus most persons would say, "The first school I was at," and not "The first school which I was at." This omission is condemned by some grammarians, but is authorised by the usage of our best writers. The omission however seems only admissible in familiar speaking and writing, and is a great defect in any composition of a serious or elevated character.

RELATOR. [INFORMATION.]

RELEASE. "Releases are in divers manners, namely: releases of all the right which a man hath in lands or tenements; and releases of actions personals and reals, and other things." (Litt. § 444.)

The former kind of release may be considered as a species of conveyance, and the instrument of release must be a deed. The operative words of release are *remise*, *release*, *renounce*, and for ever *quit claim* (an abbreviation or corruption of *quietum clamasse*). According to Littleton (§ 508) a release to a man of all demands is the best release that can be made, "and shall enure most to his advantage;" but Coke remarks that "claims" is a word of still more extensive import. The parties to a release are the releasor and releasee: the releasor is he who quits or renounces that which he has; the releasee is he who acquires what the other gives up, but he cannot acquire anything by the release, unless he has some estate in or right to the thing which is the object of the release.

Releases are either of an estate in land or of a right to land; or they are releases of things personal. Releases of estates in or rights to land require to be considered separately.

In order that a release of an estate in land may have its intended effect, there must be privity of estate between the releasor and releasee; that is, the estates of the releasor and releasee must have been acquired by the same conveyance or title, or the one estate must have been derived immediately out of the other. There must be this privity whenever the release of an estate operates either by way of enlarging the estate of the releasee, or by way of passing to him the estate of the releasor.

It is not in all cases necessary that the person to whom the release is made should be in the actual possession of the land or that he should have the estate immediately preceding that of the releasor. If land be given by C, who is tenant in fee simple, to A for years, remainder to B for life, C may release his reversion either to A or to B: in the former case A will acquire the reversion expectant on B's life estate; and in the latter case B's remainder will merge in the reversion, which will become an estate in possession on the determination of A's estate. This is commonly called a release which enlarges an estate; but in the case supposed, if the release is made to A, his estate is not thereby enlarged, and the effect is just the same as if C made him a grant of the reversion. The rule of law is undoubtedly true that "whenever a release doth enure by way of enlarging an estate, there must be privity of estate, as between lessor and lessee, donor and donee" (Co. Litt., 273, a); but there must also be privity, as in the case supposed, when no enlargement of the estate is made by the release. If C, tenant in fee simple, had originally granted the estate to B for life, and B had made a lease for years to A, a release of the reversion in fee from C to A would have no effect as a release, because there is no privity of estate, as above defined, between A and C. Such a release may, however, operate as a grant of the reversion, if there are sufficient words for that purpose. When lands are in possession of a lessee at will, for years, or for life, or of an assignee of such lessee, the lessor may release either to the lessee himself, or to his assignee. But a release by the original lessor to an under-lessee, as above stated, will not operate as a release.

In order that the release may operate to the enlargement of the estate of the releasee, it must contain proper words. Therefore if he who has the fee in reversion or remainder intends to release his estate to a tenant for years or for life, he must release to such tenant and his heirs. If he simply release to the tenant for life, the releasee will have no greater estate than he had before; and if he simply release to the tenant for years, the tenant acquires the estate only for life. (Litt., 468.)

If a lease is made, at common law, of lands in possession, the lessee has no estate till he enters, and therefore can accept no release from the lessor; but a release from the lessor to the lessee before entry of all his right in the land, extinguishes the rent.

A release may operate by passing the releasor's estate to the releasee, without enlarging the estate which the releasee already has; and this takes place in the case of joint tenants and coparceners. Joint tenants of an estate have one undivided title, and they can only convey their estates to one another by release. Coparceners have only one title, for they all make one heir, but they also transmit to their heirs separate estates. Accordingly coparceners can either release to each other or convey their estates by feoffment. In these cases it is not necessary to use any words of limitation in the release, for as the joint tenants and coparceners have all one title to their estate, whatever it may be, a release from one to another passes all the estate of the former to the latter, without any words of inheritance.

If there are three joint-tenants, and one of them releases his estate to another of them, such other becomes joint-tenant of two-thirds of the land with the remaining tenant, and he holds the released one-third as tenant in common with his remaining companion. If a lease be made to two persons, one may release to the other before entry; for there is privity of estate between them, and the release does not operate by enlargement, but by extinguishment of a right.

A man may release all his right in or to lands, and such release will comprehend all his rights at the time, but not future rights. An expectant heir cannot release the right which he may have to his ancestor's estate. A right, in order to be capable of being released, must therefore be an existing right and not a possibility. Sometimes, however, a release, though it cannot operate as such, may operate as an estoppel. In a particular case (Bensley *v.* Burdon, 2 S. and S., 519) a son was estopped under a release made by him in his father's lifetime, by the allegation of a particular fact, which was held to conclude the son who made it.

A right may be released to any person who has an estate in the land, either in possession, reversion, or remainder; but if the right be to an estate of freehold, it can only be released to a person who has an estate of freehold. Such a release will be for the benefit of all persons who are entitled to the land by the same means as the releasee.

There is also release by act or operation of law, as it is termed; that is, from certain acts or events, which are not a direct release, the legal conclusion of a release follows. Instances of this kind of release often occurred in former times, when disseisins were common, and the following is given as an example: if a disseisee disseise the heir of the disseisor, and make a feoffment, this amounts to a release of the right. (Co. Litt., 264, b.)

A Release, not considered as an instrument of conveyance, is the giving up or discharging of a right of action or suit which one man has against another. This release may be either by act of law or by deed.

If a creditor makes his debtor his executor or one of his executors, the debt is legally extinguished as soon as the creditor dies, though there can be no legal evidence of this extinguishment until the executor has obtained probate of the will. The ground of this legal conclusion is, the union of creditor and debtor in the person of the executor, who would be a necessary party to an action at law against himself. But in equity so far is the debtor from being released, that the debtor executor is considered to have received the debt, and to have it as assets in his hands. Accordingly in a suit in equity against him, he may be ordered to pay the amount of the debt into court, upon admitting it in his answer. If a debtor appoint his creditor his executor, the creditor executor, both at law and in equity, may retain his debt out of the assets which come to his hands, provided he does not thereby prejudice creditors of a superior degree. If a woman marries her debtor or creditor, the extinguishment of the debt is a necessary consequence.

In a release of this kind also the proper words are *remise, release,* and *quit-claim*, but any words are sufficient for the purpose which clearly express the intention of the parties to the deed. If a man covenants with another that he will never sue him, this is legally construed to be equivalent to a release, because the same end would be ultimately effected by virtue of this covenant, as if there were an absolute release. But there are cases in which a perpetual covenant not to sue one debtor will not discharge a co-debtor. (Hutton *v.* Eyre, 6 Taunt., 289.) A covenant not to sue for a limited time cannot of course have the effect of a release.

All persons may release, who are not under some legal disability, such as infancy. A husband may release a debt due to his wife, because he is the person entitled to receive it; but his release of a debt due to the wife extends only to such debts as are demands at the time of the release. A partner, or other co-debtee, may also release a debt due to him and his co-partners. An executor may, at law, release a debt due to him and his co-executors as such; and one of several administrators has the same power: but such releases are ineffectual in equity, unless they are made in the due discharge of the executor's duty. Though one of several co-plaintiffs may release a cause of action, a court of law will set aside the release, if it is a fraudulent transaction.

A release may be set aside in equity on the ground of fraud, a term which will include every act of commission or omission that renders the transaction unfair, such as misrepresentation or suppression of facts important to be known to the releasor. A plea of a release is no answer to a bill in equity which seeks to set aside the release on the ground of fraud, or which, anticipating a plea of the release, charges that it was fraudulently obtained, unless the fraud which is charged is put in issue in the plea, and sufficiently denied by answer. The principle of this is fully and clearly stated by Lord Redesdale. (Roche *v.* Morgell, 2 Scho. and Lef., 730.)

The releasor may have demands against another, both in his own right and in another right, such as that of executor for instance; and accordingly a question sometimes arises whether the release extends to demands in both rights, when the release contains no clear declaration of the demands to which it extends. If this ambiguity exists, it seems to be settled that the release will only extend to such claims as the releasor has in his own right, if he has any demands in both rights; but if he has only demands in right of another, the release will operate upon them. If a man who has a rent-charge issuing out of a certain number of acres of land, releases his right in any part of the land, he releases all the rent, for it is charged on all the land, and not on any part. A release of all demands means all demands which exist at the time of the release, and it does not extend to anything which, at the time of the release, is not a demand, but afterwards becomes a demand. It is generally considered that a release of all demands would extend to a rent-charge, or a rent-service, parcel of a seignory in gross (but not to a rent-service incident to a reversion), but a release of all actions could not extend further than to a release of arrears of rent then due. Though a release of all actions is not a release of a sum of money not then due, it is said that such a release made before the day of payment appointed by the condition of a bond would be effectual; a bond being an acknowledgment of a present debt, defeasible by a condition subsequent, which does not prevent the right of action from vesting in the mean time.

A release is generally so expressed as to include all demands up to the day of the date of it; but in this case the day of the date is excluded from the computation. If the release extends to all demands up to the making of the release, this will comprehend all demands up to the delivery of it.

It is usual for releases to contain very general words, which, in their literal signification, may comprehend things that the releasor does not intend to release. But whenever it can be clearly shown, as for instance by a particular recital in a deed, that the general words of release were intended to be limited, such construction must be put on them. Parol evidence is not admissible for the purpose of limiting or enlarging the words of a release; but, as in the case of wills, it may be admitted where a difficulty arises in applying the words of the instrument to the facts of the case, for which purpose the state of the facts at the time of the release must be ascertained by extrinsic evidence.
